## The Lovasz Local Lemma

Let $A_{1}, \ldots, A_{n}$ be a set of "bad" events. We want to show that

$$
\operatorname{Pr}\left(\cap_{i=1}^{n} \bar{A}_{i}\right)>0 .
$$

(1) If $\sum_{i=1}^{n} \operatorname{Pr}\left(A_{i}\right)<1$ then $\operatorname{Pr}\left(\cap_{i=1}^{n} \bar{A}_{i}\right)>0$.
(2) If all the $A_{i}$ 's are mutually independent and for all $i$ $\operatorname{Pr}\left(A_{i}\right)<1$ then $\operatorname{Pr}\left(\cap_{i=1}^{n} \bar{A}_{i}\right)=\prod_{i=1}^{n} \operatorname{Pr}\left(\bar{A}_{i}\right)>0$..
(3) If each $A_{i}$ depends only on a few other events: The Lovasz Local Lemma.

## Definition

An event $E$ is mutually independent of the events $E_{1}, \ldots, E_{n}$, if for any $T \subset[1, \ldots, n]$,

$$
\operatorname{Pr}\left(E \mid \cap_{j \in T} E_{j}\right)=\operatorname{Pr}(E)
$$

## Definition

A dependency graph for a set of events $E_{1}, \ldots, E_{n}$ has $n$ vertices $1, \ldots, n$. Events $E_{i}$ is mutually independent of any set of events $\left\{E_{j} \mid j \in T\right\}$ iff there is no edge in the graph connecting $i$ to any $j \in T$.

## Theorem

Let $E_{1}, \ldots, E_{n}$ be a set of events. Assume that
(1) For all $i, \operatorname{Pr}\left(E_{i}\right) \leq p$;
(2) The degree of the dependency graph is bounded by $d$.
(3) $4 d p \leq 1$
then

$$
\operatorname{Pr}\left(\cap_{i=1}^{n} \bar{E}_{i}\right)>0 .
$$

Let $S \subset\{1, \ldots, n\}$. We prove by induction on $s=0, \ldots, n-1$ that if $|S| \leq s$, for all $k$

$$
\operatorname{Pr}\left(E_{k} \mid \cap_{j \in S} \bar{E}_{j}\right) \leq 2 p
$$

For $s=0, S=\emptyset$ obvious.
W.I.o.g. renumber the events so that $S=\{1, \ldots, s\}$, and $(k, j)$ is not and edge of the dependency graph for $j>d$.

$$
\begin{aligned}
\operatorname{Pr}\left(E_{k} \mid \bigcap_{j=1}^{s} \bar{E}_{j}\right) & =\frac{\operatorname{Pr}\left(E_{k} \cap \bigcap_{j=1}^{s} \bar{E}_{j}\right)}{\operatorname{Pr}\left(\bigcap_{j=1}^{s} \bar{E}_{j}\right)} \\
& =\frac{\operatorname{Pr}\left(E_{k} \cap \bigcap_{j=1}^{d} \bar{E}_{j} \mid \bigcap_{j=d+1}^{s} \bar{E}_{j}\right) \operatorname{Pr}\left(\bigcap_{j=d+1}^{s} \bar{E}_{j}\right)}{\operatorname{Pr}\left(\bigcap_{j=1}^{d} \bar{E}_{j} \mid \bigcap_{j=d+1}^{s} \bar{E}_{j}\right) \operatorname{Pr}\left(\bigcap_{j=d+1}^{s} \bar{E}_{j}\right)} \\
& =\frac{\operatorname{Pr}\left(E_{k} \cap \bigcap_{j=1}^{d} \bar{E}_{j} \mid \bigcap_{j=d+1}^{s} \bar{E}_{j}\right)}{\operatorname{Pr}\left(\bigcap_{j=1}^{d} \bar{E}_{j} \mid \bigcap_{j=d+1}^{s} \bar{E}_{j}\right)}
\end{aligned}
$$

$$
\operatorname{Pr}\left(E_{k} \cap \bigcap_{j=1}^{d} \bar{E}_{j} \mid \bigcap_{j=d+1}^{s} \bar{E}_{j}\right) \leq \operatorname{Pr}\left(E_{k} \mid \bigcap_{j=d+1}^{s} \bar{E}_{j}\right)=\operatorname{Pr}\left(E_{k}\right) \leq p
$$

Using the induction hypothesis we prove:

$$
\begin{aligned}
\operatorname{Pr}\left(\bigcap_{j=1}^{d} \bar{E}_{j} \mid \bigcap_{j=d+1}^{s} \bar{E}_{j}\right) & \geq 1-\sum_{i=1}^{d} \operatorname{Pr}\left(E_{i} \mid \bigcap_{j=d+1}^{s} \bar{E}_{j}\right) \\
& \geq 1-\sum_{i=1}^{d} 2 p \\
& \geq 1-2 p d \geq 1 / 2
\end{aligned}
$$

$$
\operatorname{Pr}\left(E_{k} \mid \bigcap_{j=1}^{s} \bar{E}_{j}\right) \leq \frac{p}{1 / 2}=2 p
$$

Now we can complete the proof:

$$
\begin{gathered}
\operatorname{Pr}\left(\bigcap_{j=1}^{n} \bar{E}_{j}\right)=\Pi_{i=1}^{n} \operatorname{Pr}\left(\bar{E}_{i} \mid \bigcap_{j=1}^{i-1} \bar{E}_{j}\right) \\
=\Pi_{i=1}^{n}\left(1-\operatorname{Pr}\left(E_{i} \mid \bigcap_{j=1}^{i-1} \bar{E}_{j}\right)\right) \geq \Pi_{i=1}^{n}(1-2 p)>0 .
\end{gathered}
$$

## Application: Edge-Disjoint Paths

Assume that $n$ pairs of users need to communicate using edge-disjoint paths on a given network.
Each pair $i=1, \ldots, n$ can choose a path from a collection $F_{i}$ of $m$ paths.

## Theorem

If for each $i \neq j$, any path in $F_{i}$ shares edges with no more than $k$ paths in $F_{j}$, where $\frac{8 n k}{m} \leq 1$, then there is a way to choose $n$ edge-disjoint paths connecting the $n$ pairs.

## Proof

Consider the probability space defined by each pair choosing a path independently uniformly at random from its set of $m$ paths. $E_{i, j}=$ the paths chosen by pairs $i$ and $j$ share at least one edge. A path in $F_{i}$ shares edges with no more than $k$ paths in $F_{j}$,

$$
p=\operatorname{Pr}\left(E_{i, j}\right) \leq \frac{k}{m}
$$

Let $d$ be the degree of the dependency graph.
Since event $E_{i, j}$ is independent of all events $E_{i^{\prime}, j^{\prime}}$ when $i^{\prime} \notin\{i, j\}$ and $j^{\prime} \notin\{i, j\}$, we have $d<2 n$.

$$
4 d p<\frac{8 n k}{m} \leq 1
$$

$$
\operatorname{Pr}\left(\cap_{i \neq j} \overline{E_{i, j}}\right)>0 .
$$

## Lemma

Let $G^{\prime}$ be the dependency graph on the surviving clauses. With high probability all connected components in $G^{\prime}$ have size $O(\log m)$.

## Part Two:

Using exhaustive search assign values to the deferred variable to complete the truth assignment for the formula. If a connected component has $O(\log m)$ clauses it has $O(k \log m)$ variables. Assuming $k=O(1)$ we can check all assignments in polynomial in $m$ number of steps.

## Lemma

There is an assignment of values to the deferred variables such that all the surviving clauses are satisfied (thus the formula is satisfied).

At the end of the first phase we have $m^{\prime}$ "surviving clauses' (all the rest are satisfied), each surviving clause has at least $k / 2$ deferred variables.
Consider a random assignment of the deferred variables.
Let $E_{i}$ be the event clause $i$ (of the surviving clauses) is not satisfied.

$$
p=\operatorname{Pr}\left(E_{i}\right) \leq 2^{-k / 2}
$$

The degree of the dependency graph is bounded by

$$
d=k T<k 2^{\alpha k} .
$$

Since

$$
4 d p \leq 4 k 2^{\alpha k} 2^{-k / 2} \leq 1
$$

there is a satisfying assignment of the deferred variables that (together with the assignment of the other variables) satisfies the formula.

Let $G^{\prime}$ be the dependency graph on the surviving clauses. With high probability all connected components in $G^{\prime}$ have size
$O(\log m)$.
Assume that there is a connected component $R$ of size $r=|R|$.
Since the degree of a vertex in $R$ is bounded by $d$, there must be a set $R^{\prime}$ of $\left|R^{\prime}\right|=r / d^{3}$ vertices in $R$ which are at distance at least 4 from each other.
A clause "survives" the first part if it is at distance at most 1 from a dangerous clause. Thus, for each clause in $R^{\prime}$ there is a distinct dangerous clause, and these dangerous clauses are at distance 2 from each other.

The probability that a given clause is dangerous is at most $2^{-k / 2}$. The probability that a given clause $C$ survives is at most $(d+1) 2^{-k / 2}$ ( $C$ must be unsatisfied after the first phase and either $C$ is dangerous or at least one of its neighbours must be dangerous).
These events are independent for vertices in $R^{\prime}$. Thus the probability of a particular connected component of $r$ vertices is bounded by

$$
\left((d+1) 2^{-k / 2}\right)^{r / d^{3}}
$$

How many possible connected components of size $r$ are in a graph of $m$ nodes and maximum degree $d$ ?

## Lemma

There are no more than $\mathrm{md}^{2 r}$ possible connected components of size $r$ in a graph of $m$ vertices and maximum degree $d$.

## Proof.

A connected component of size $r$ has a spanning tree of $r-1$ edges.
We can choose a "root" for the tree in $m$ ways.
A tree can be defined by an Euler tour that starts and ends at the root and traverses each edge twice.
At each node the tour can continue in up to $d$ ways. Thus, for a given root there are no more than $d^{2 r}$ different Euler tours.

Thus, the probability that at the end of the first phase there is a connected component of size $r=\Omega(\log m)$ is bounded by

$$
m d^{2 r}\left((d+1) 2^{-k / 2}\right)^{r / d^{3}}=o(1)
$$

for $d=k 2^{\alpha k}, \alpha>0$ sufficiently small.

Each deferred variable appears in only one component. A component of size $O(\log m)$ has only $O(\log m)$ variables. Thus, we can enumerate (try) all possibilities in time polynomial in $m$.

Theorem

Given a CNF formula of $m$ clauses, each clause has $k=O(1)$ literals, each variables appears in up to $2^{\alpha k}$ clauses. For a sufficiently small $\alpha>0$ there is an algorithm that finds a satisfying assignment to the formula in time polynomial in $m$.
