# The Euler Phi Function

- Definition:

For a positive integer  $n$ , if  $0 < a < n$  and  $\gcd(a, n) = 1$ ,  $a$  is **relatively prime** to  $n$ .

- Definition:

Given an integer  $n$ ,  $\varphi(n)$  is the number of positive integers less than or equal to  $n$  and relatively prime to  $n$ .

# The Euler Phi Function

- Theorem: Formula for  $\varphi(n)$

Let  $p$  be prime,  $e, m, n$  be positive integers

1)  $\varphi(p) = p-1$

2) if  $\gcd(m,n)=1$ , then  $\varphi(mn)=\varphi(m)\varphi(n)$

3)  $\varphi(p^e) = p^e - p^{e-1}$

4) If  $n = p_1^{e_1} p_2^{e_2} \dots p_k^{e_k}$  then

$$\varphi(n) = n \left(1 - \frac{1}{p_1}\right) \left(1 - \frac{1}{p_2}\right) \dots \left(1 - \frac{1}{p_k}\right)$$

# Fermat's Little Theorem

- Fermat's Little Theorem

If  $p$  is a prime number and  $a$  is a natural number that is not a multiple of  $p$ , then

$$a^{p-1} \equiv 1 \pmod{p}$$

# Euler's Theorem

- Euler's Theorem

Given integer  $n > 1$ , such that  $\gcd(a, n) = 1$  then

$$a^{\varphi(n)} \equiv 1 \pmod{n}$$

- Corollary

Given integer  $n > 1$ , such that  $\gcd(a, n) = 1$  then

$a^{\varphi(n)-1} \pmod{n}$  is a multiplicative inverse of  $a \pmod{n}$ .

# Consequence of Euler's Theorem

- Principle of Modular Exponentiation

Given integer  $n > 1$ ,  $x, y$ , and a positive integers with  $\gcd(a, n) = 1$ . If  $x \equiv y \pmod{\varphi(n)}$ , then

$$a^x \equiv a^y \pmod{n}$$

- Proof idea:

$$a^x = a^{k\varphi(n)+y} = a^y (a^{\varphi(n)})^k$$

by applying Euler's theorem we obtain

$$a^x \equiv a^y \pmod{n}$$

# Diffie-Hellman Key Exchange

- Diffie-Hellman proposed a cryptographic protocol to exchange keys among two parties in 1976.
  - Public parameters:
    - p: A large prime
    - g: Base (generator)
  - Secret parameters:
    - $\alpha, \beta \in \{0, 1, 2, \dots, p-2\}$

# Security of Diffie-Hellman

- Discrete Logarithm Problem (DLP):
  - Given  $p, g, g^\alpha \bmod p$ , what is  $\alpha$ ?
  - easy in  $\mathbb{Z}$ , hard in  $\mathbb{Z}_p$
- Diffie-Hellman Problem (DHP):
  - Given  $p, g, g^\alpha \bmod p, g^\beta \bmod p$ , what is  $g^{\alpha\beta} \bmod p$ ?
- DHP is as hard as DLP.

# Commutative Encryption

- Definition:

An encryption scheme is commutative if

$$E_{K_1}[E_{K_2}[M]] = E_{K_2}[E_{K_1}[M]]$$

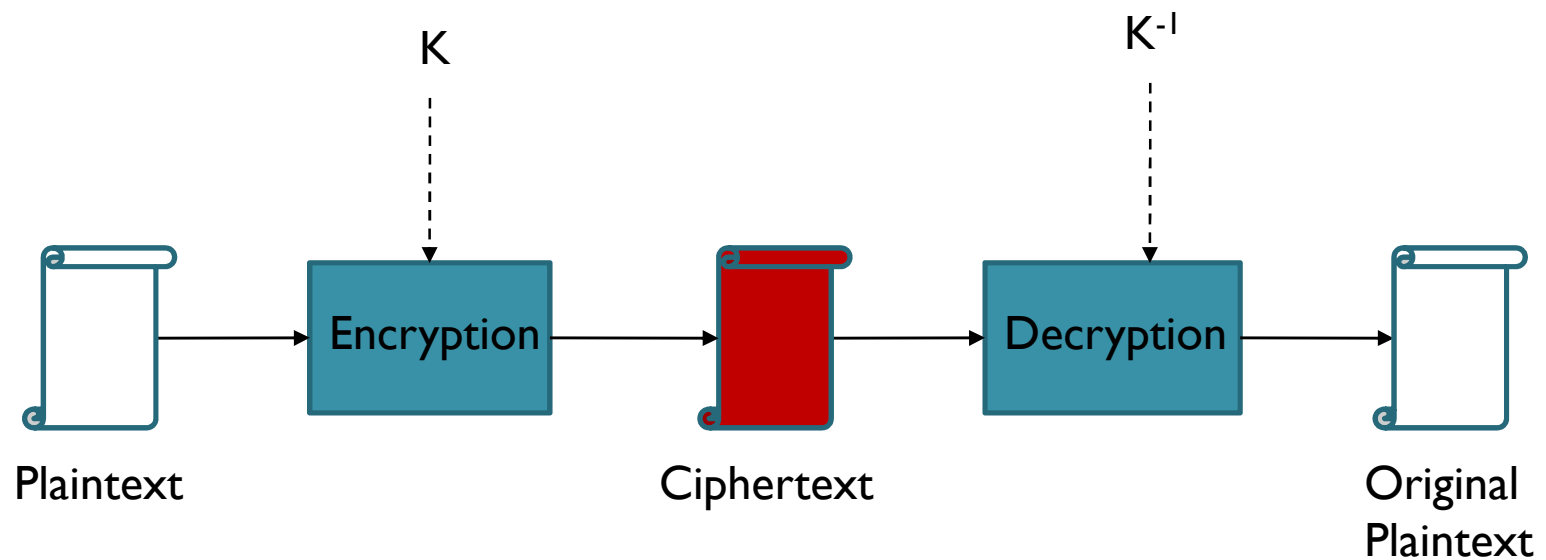

Given a commutative encryption scheme, then

$$D_{K_1}[D_{K_2}[E_{K_1}[E_{K_2}[M]]] = M$$

- Most symmetric encryption schemes are not commutative such as DES and AES.

# Asymmetric Encryption Functions

- An asymmetric encryption function:
  - Encryption ( $K$ ) and decryption ( $K^{-1}$ ) keys are different.
  - Knowledge of the encryption key is not sufficient for deriving the decryption key efficiently.
  - Hence, the encryption key can be made “public”.

# Pohlig-Hellman Exponentiation Cipher

- A **commutative** exponentiation cipher
  - encryption key  $(e, p)$ , where  $p$  is a prime
  - decryption key  $(d, p)$ , where  $ed \equiv 1 \pmod{(p-1)}$  or in other words  $d \equiv e^{-1} \pmod{(p-1)}$
  - to encrypt  $M$ , compute  $C = M^e \pmod p$
  - to decrypt  $C$ , compute  $M = C^d \pmod p = M^{ed} \pmod p$

# Public Key Encryption

- Each party has a PAIR  $(K, K^{-1})$  of keys:
  - $K$  is the public key
  - $K^{-1}$  is the private key

$$D_{K^{-1}}[E_K[M]] = M$$

- The public-key  $K$  may be made publicly available.
- Many can encrypt with the public key, only one can decrypt.
- Knowing the public-key and the cipher, it is computationally **infeasible to compute the private key**.

# Solutions with Public Key Cryptography

- Key distribution solution:
  - Alice makes her encryption key  $K$  public
  - Everyone can send her an encrypted message:  
$$C = E_K(M)$$
  - Only Alice can decrypt it with the private key  $K^{-1}$ :  
$$M = D_{K^{-1}}(C)$$
- Source Authentication Solution:
  - Only Alice can “sign” a message, using  $K^{-1}$ .
  - Anyone can verify the signature, using  $K$ .
  - Only if such a function could be found...

# RSA Algorithm

- Invented in 1978 by Ron Rivest, Adi Shamir and Leonard Adleman
  - Published as R L Rivest, A Shamir, L Adleman, "On Digital Signatures and Public Key Cryptosystems", Communications of the ACM, vol 21 no 2, pp120-126, Feb 1978
- Security relies on the **difficulty of factoring large composite numbers**
- Essentially the same algorithm was discovered in 1973 by Clifford Cocks, who works for the British intelligence

# RSA Public Key Crypto System

- Choose large primes  $p, q$ 
  - Compute  $n = pq$  and  $\phi(n) = (q-1)(p-1)$
- Choose  $e$ , such that  $\gcd(e, \phi(n)) = 1$ .
  - Take  $e$  to be a prime
- Compute  $d \equiv e^{-1} \pmod{\phi(n)}$   $ed \equiv 1 \pmod{\phi(n)}$ 
  - **Public key:  $n, e$**
  - **Private key:  $d$**
- Encryption:  $C = E(M) = M^e \pmod{n}$   
Decryption:  $D(C) = C^d \pmod{n} = M$

# RSA Encryption

- Encryption:  $C = E(M) = M^e \bmod n$ ,
- Decryption:  $D(C) = C^d \bmod n$ .
- Why does it work?

$$\begin{aligned} D(M) &= (M^e)^d \bmod n = M^{ed} \bmod n \\ &= M^{k\varphi(n) + 1} \bmod n, \quad (\text{for some } k) \\ &= (M^{\varphi(n)})^k M \bmod n \\ &= M \end{aligned}$$

- RSA problem: Given  $n, e, M^e \bmod n$ , what is  $M$ ?
  - Computing  $d$  is equivalent to factoring  $n$ .
  - The security is based on difficulty of factoring large integers.

## RSA Example

- Let  $p = 11$ ,  $q = 7$ , then
  - $n = 77$ ,  $\varphi(n) = 60$
- Let  $e = 37$ , then
  - $d = 13$  ( $ed = 481$ ;  $ed \bmod 60 = 1$ )
- Let  $M = 15$ , then  $C \equiv M^e \pmod{n}$   
 $C \equiv 15^{37} \pmod{77} = 71$
- $M \equiv C^d \pmod{n}$   
 $M \equiv 71^{13} \pmod{77} = 15$

## RSA Implementation

- The security of RSA depends on how large  $n$  is, which is often measured in the number of bits for  $n$ .
  - Current recommendation is 1024 bits for  $n$ .
- $p$  and  $q$  should have the same bit length, so for 1024 bits RSA,  $p$  and  $q$  should be about 512 bits.
- $p$ - $q$  should not be small.
  - In general,  $p, q$  randomly selected and then tested for primality
  - Many implementations use the Rabin-Miller test, (probabilistic test)
