

# Security Handshake Pitfalls

Ahmet Burak Can

Hacettepe University

abc@hacettepe.edu.tr

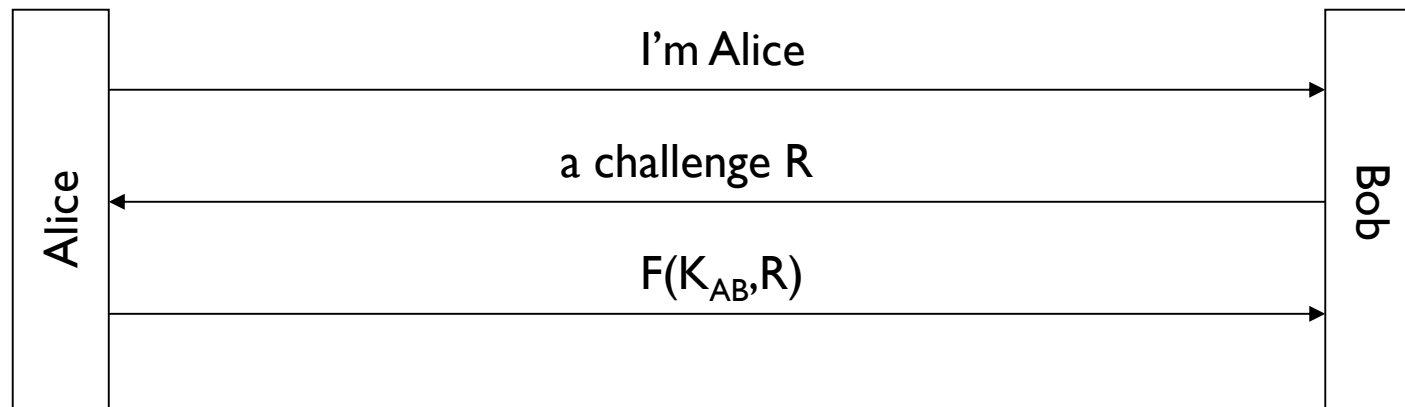

# Cryptographic Authentication

- Password authentication is subject to eavesdropping
- Alternative: Cryptographic challenge-response
  - Symmetric key
  - Public key

# Symmetric Key Challenge-Response

An example protocol:

- Authentication not mutual (login only)
- Subject to connection hijacking (login only)
- Subject to off-line password guessing (if  $K$  is derived from password)
- Bob's database has keys in the clear

# Symmetric Key Challenge-Response

An alternative protocol:

- Requires reversible cryptography
- Subject to dictionary attack, **without eavesdropping**, if  $R$  is recognizable
- Can be used for mutual authentication if  $R$  is recognizable and has limited lifetime

# Symmetric Key Challenge-Response

A one-message protocol:

- Easy integration into password-sending systems
  - More efficient: Single message, stateless
  - Care needed against replays: timeout needed
  - Care needed if key is common across servers
  - Clock has to be protected as well
- Alternatively, with a hash function, send,  
I'm Alice, timestamp,  $H(K_{AB}, \text{timestamp})$

# Public Key Challenge-Response

By signature:

# Public Key Challenge-Response

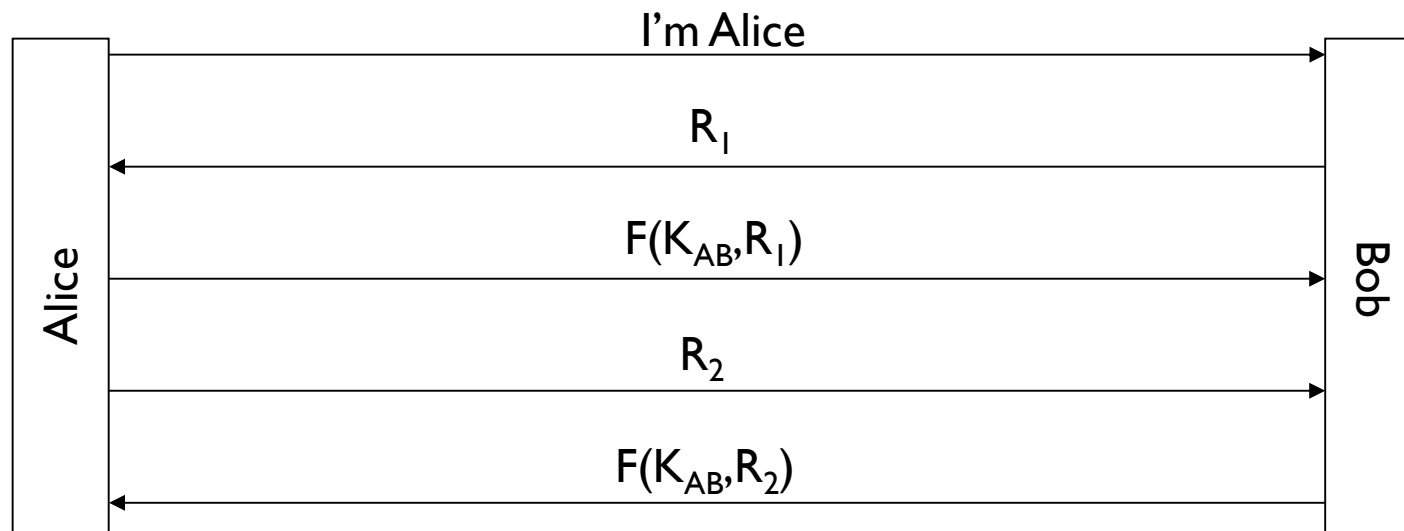

By decryption:

- Problem: Bob (or Trudy) can get Alice to sign/decrypt any text he chooses.
- Solutions:
  - Never use the same key for different purposes (e.g., for login and signature)
  - Use formatted challenges

# Mutual Authentication

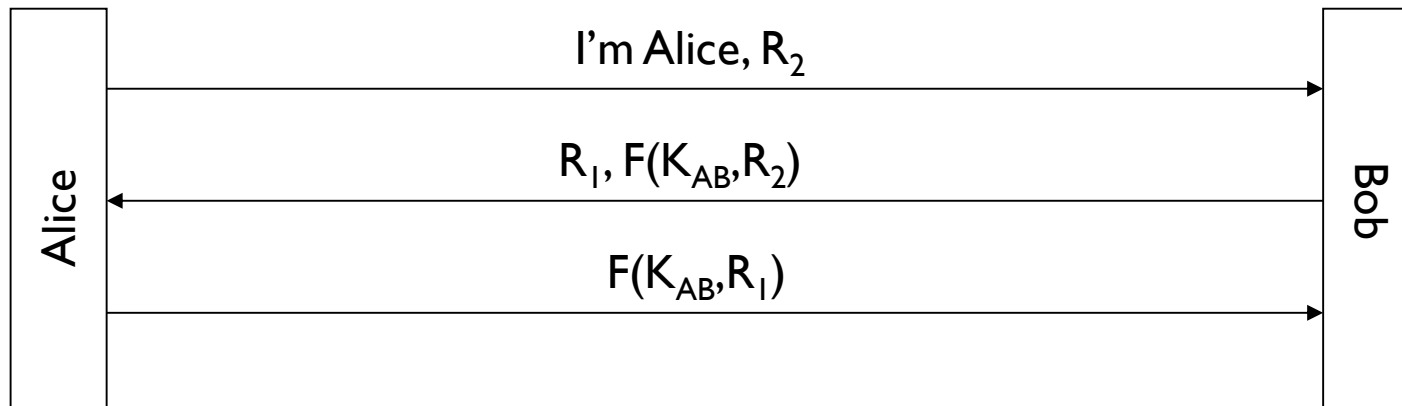

An example protocol:

# Mutual Authentication with Few Messages

Number of messages for mutual authentication can be reduced:

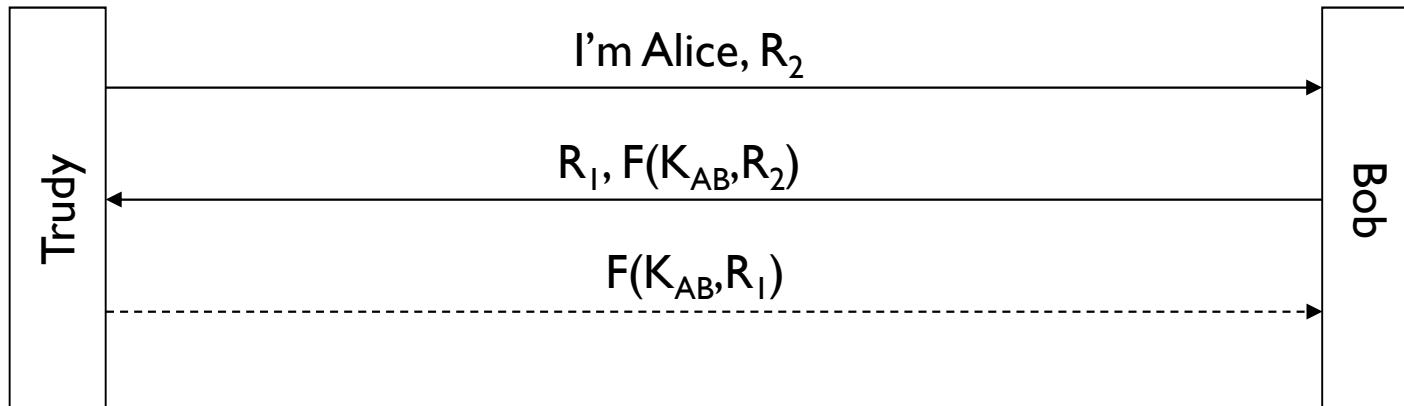

However, this protocol is vulnerable to

- Reflection attack
- Dictionary attack :Trudy can do dictionary attack against  $K_{AB}$  acting as Alice, without eavesdropping.

# Reflection Attack:

Original session:

Decoy session:

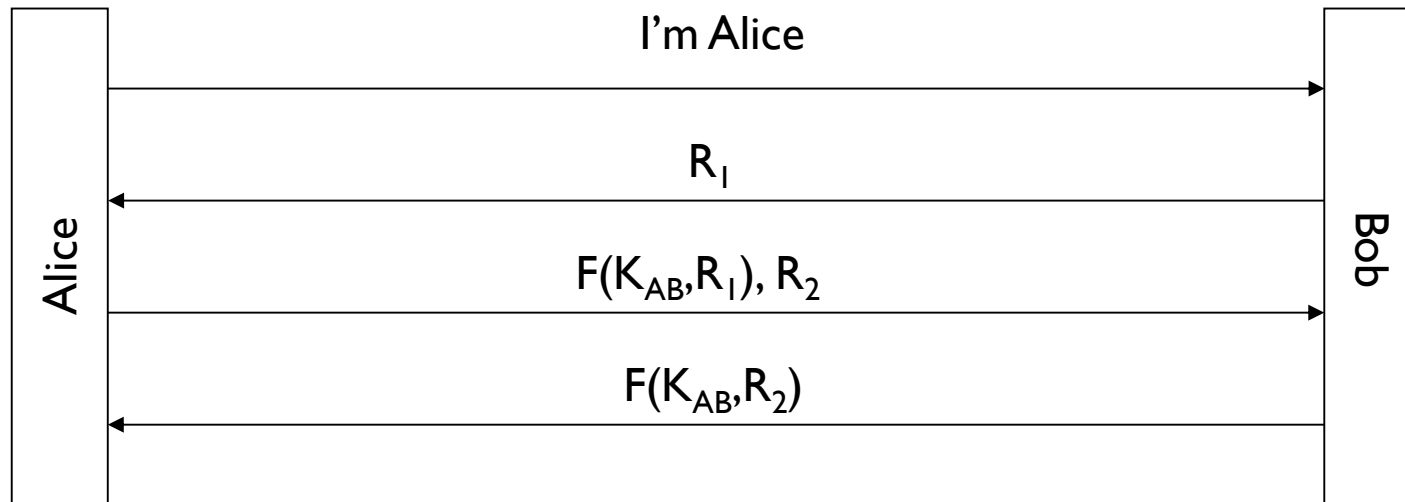

# Results from Reflection Attack

- Solutions:
  - Different keys for Alice and Bob
  - Formatted challenges, different for Alice and Bob
- Principle:
  - Initiator should be the first to prove its identity

# A Modified Mutual Authentication Scheme

- Solution against both problems:

- Dictionary attack is still possible if Trudy can impersonate Bob.

# Mutual Authentication with Public Keys

- Problem: How can the public/private keys be remembered by ordinary users?
- Possibly, they can be retrieved from a server with password based authentication & encryption.

# Session Key Establishment

- A **session key** is needed for integrity protection and encryption in a communication session. It must be
  - different for each session
  - unguessable by an eavesdropper
  - not  $K_{AB}\{x\}$  for some  $x$  predictable/extractable by an attacker
- Session keys can be established by using
  - Symmetric encryption
  - Public key encryption

# Session Key Establishment with Symmetric Encryption

- Do not use  $K_{AB}\{R\}$  or  $K_{AB}\{R+I\}$ 
  - Take  $(K_{AB}+I)\{R\}$  as the session key.

# Session Key Establishment with Public Key Cryptosystem

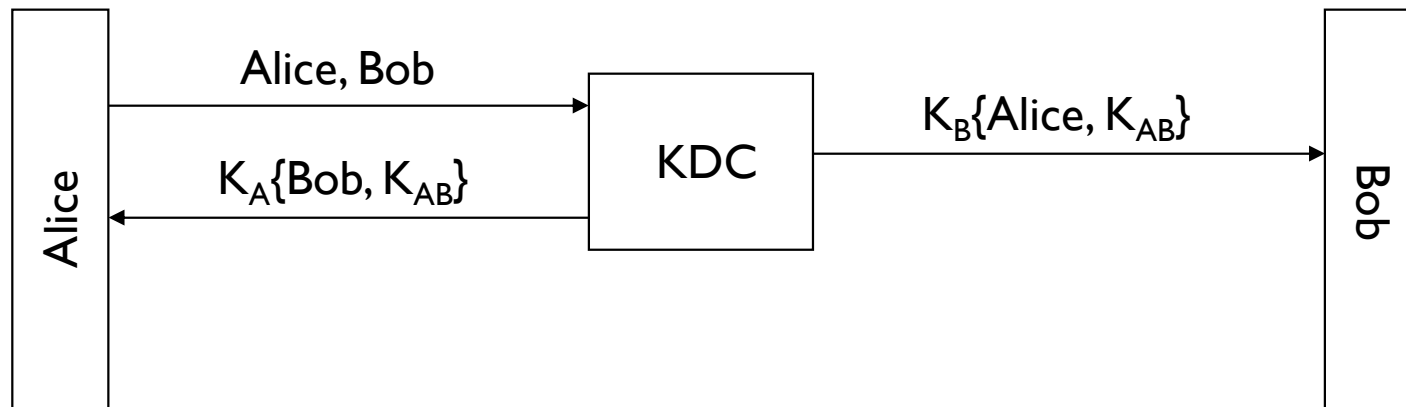

- An alternative is to use Diffie-Helman key exchange algorithm.
- Another alternative with PKC, send additional random nonces  $\{R\}_A$  ,  $\{R\}_B$  and use them to derive a session key.

# Key Establishment and Authentication with KDC

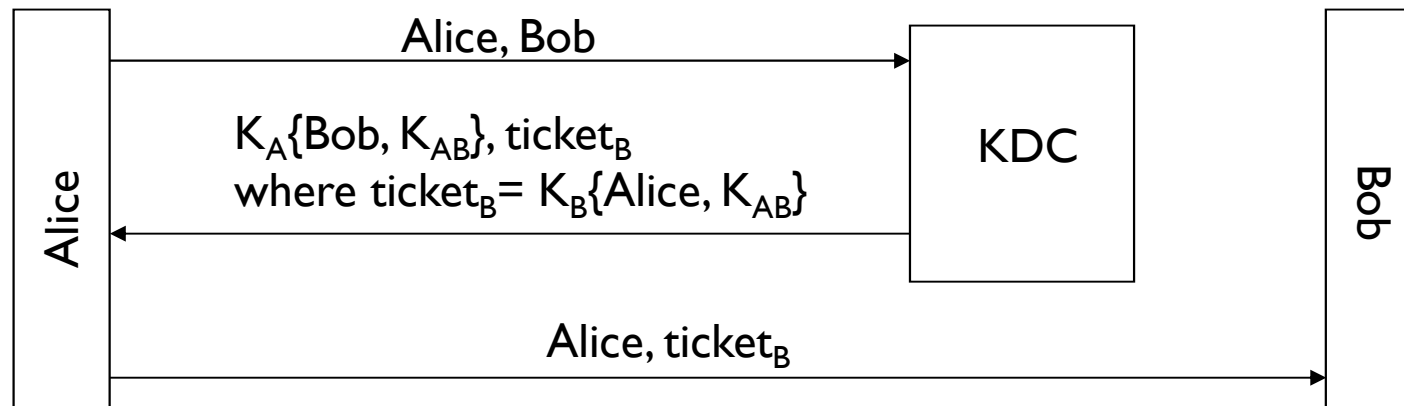

A simple protocol:

- Problem:
  - Potential delayed key delivery to Bob. (besides others)

# Key Establishment and Authentication with KDC

- Another simple protocol:

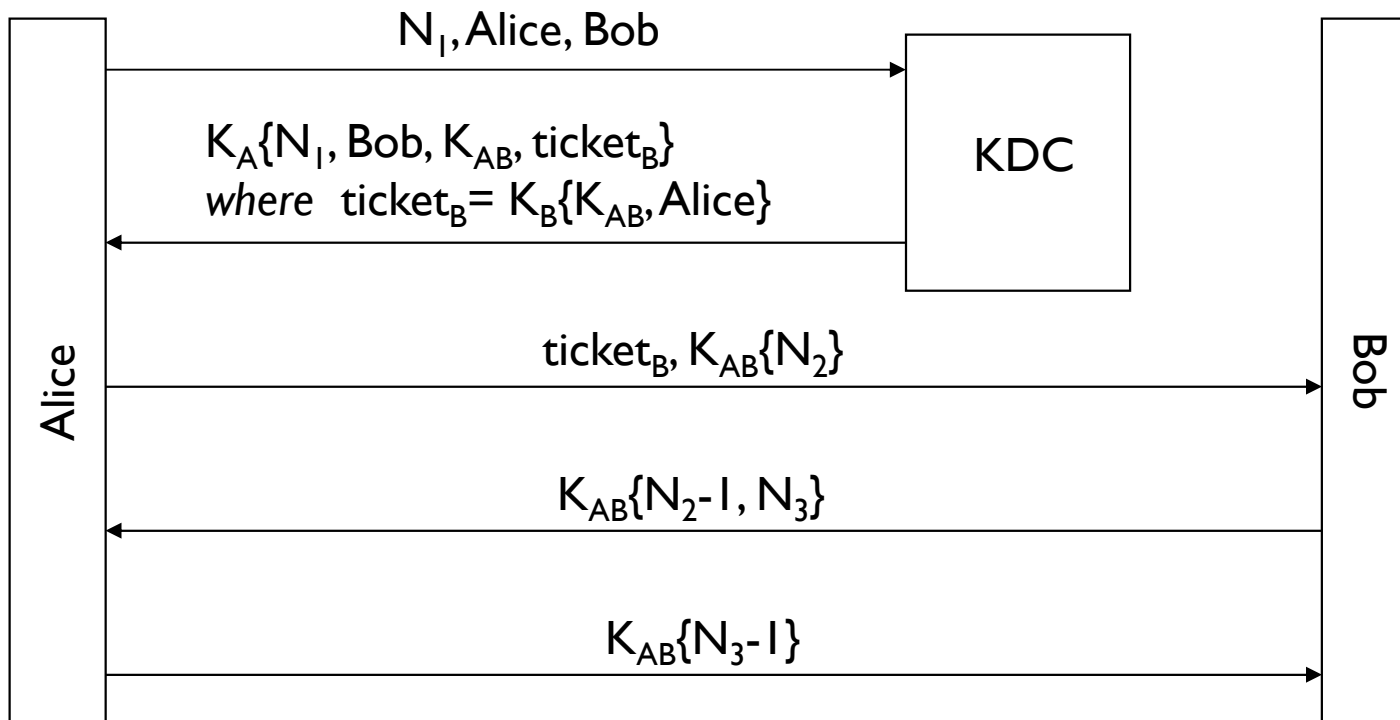

- Problems:
  - No freshness guarantee for  $K_{AB}$
  - Alice & Bob need to authenticate

# Nonces

- Nonce: Something created for one particular occasion
- Nonce types:
  - Random numbers
  - Timestamps
  - Sequence numbers
- Random nonces needed for unpredictability
- Obtaining random nonces from timestamps: encryption with a secret key.

# Needham-Schroeder Protocol

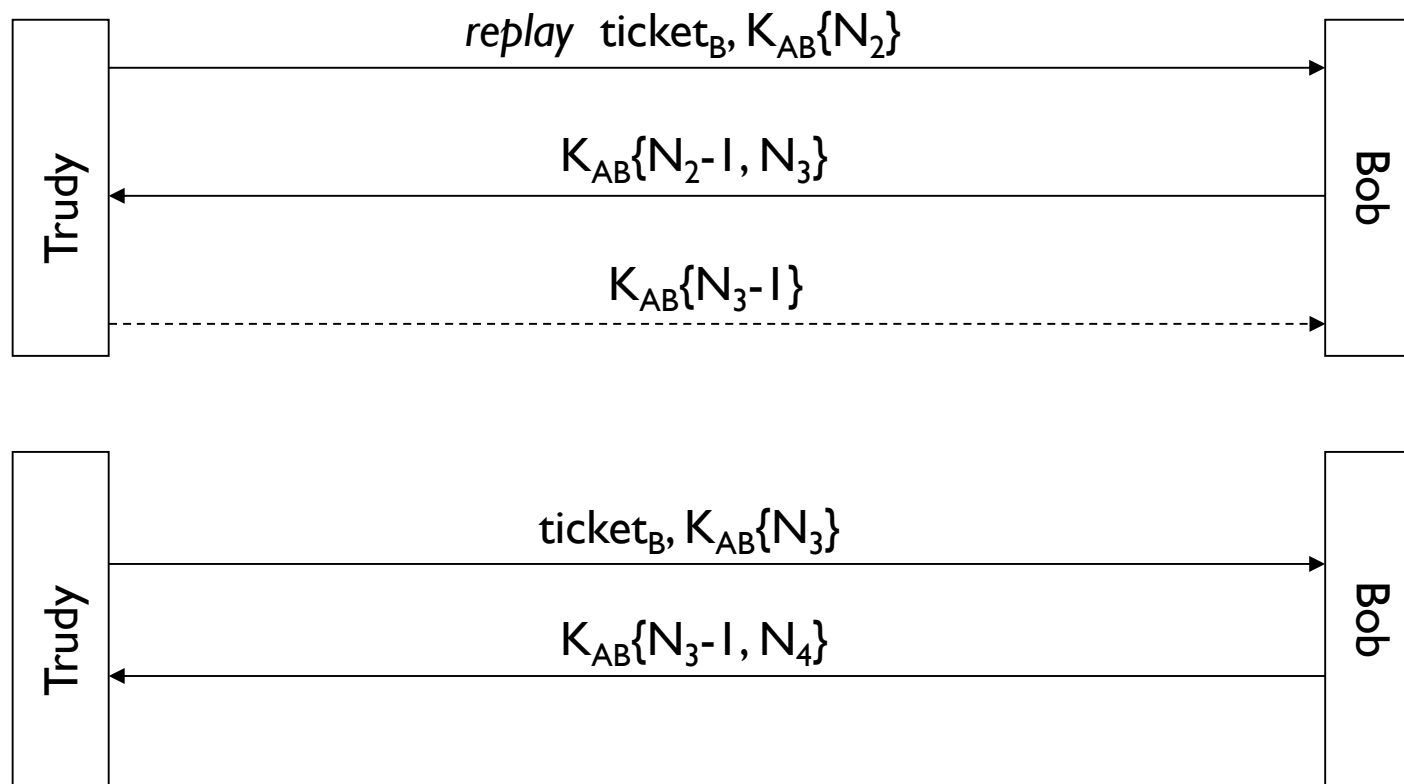

# Needham-Schroeder Protocol

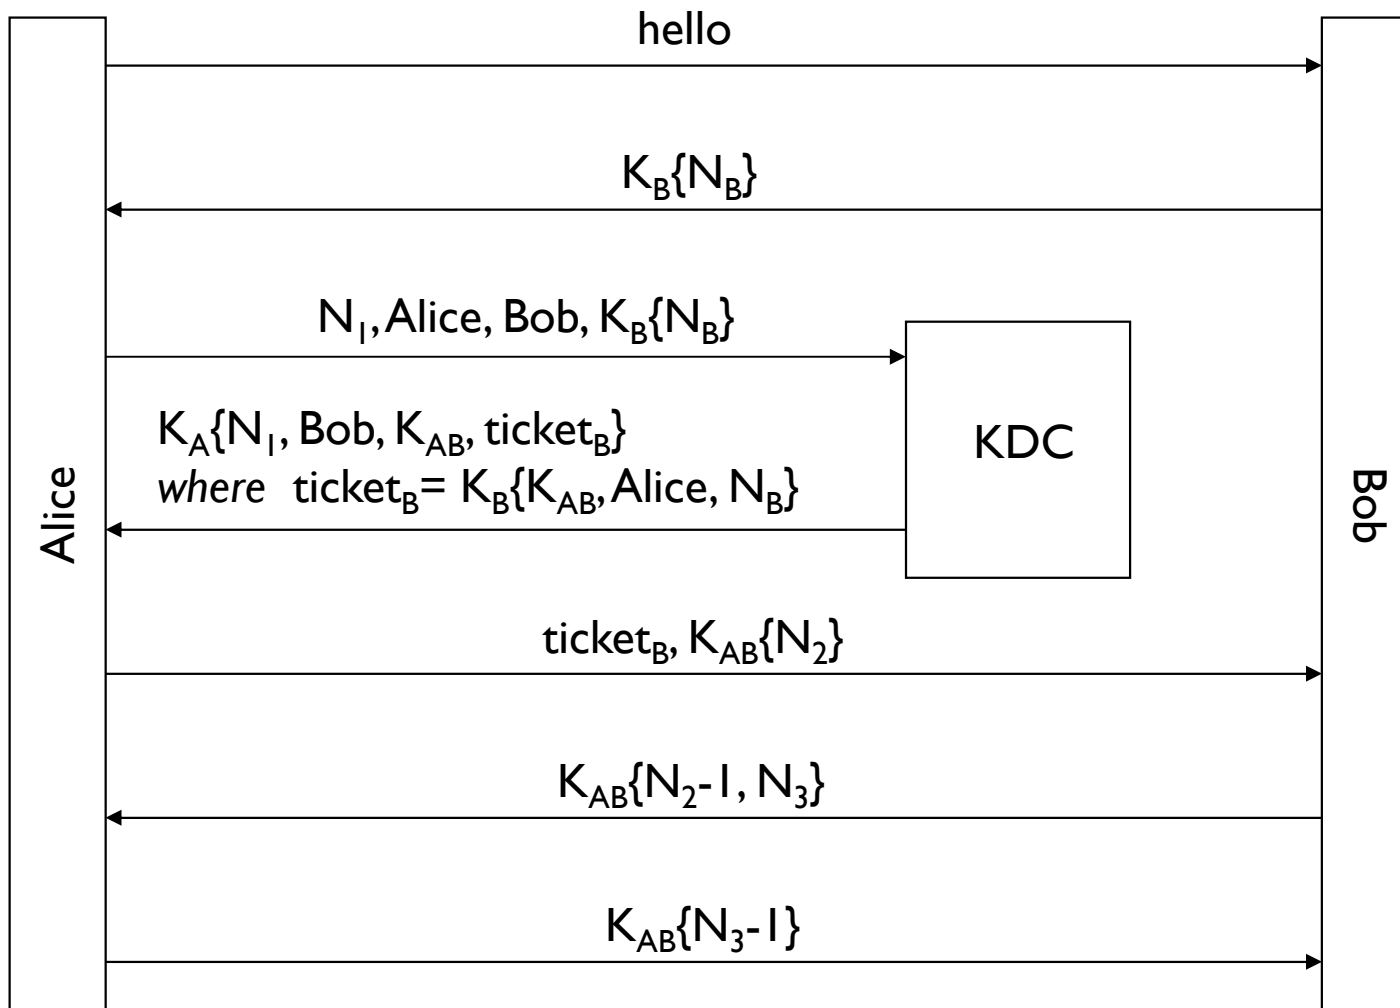

- Ticket is double-encrypted. (unnecessary)
- $N_1$ : for authenticating KDC & freshness of  $K_{AB}$ .
- $N_2, N_3$ : for key confirmation, mutual authentication
- Why are the challenges  $N_2, N_3$  encrypted?
- Problem: Bob doesn't have freshness guarantee for  $K_{AB}$  (i.e., can't detect replays).

# Replaying Tickets

- Messages should be integrity protected. Otherwise, cut-and-paste reflection attacks possible:

# Expanded Needham-Schroeder Protocol

# Protocol Performance Comparison

- **Computational Complexity:**  
(to minimize CPU time, power consumption)
  - Number of private-key operations
  - “ “ public-key “
  - “ “ bytes encrypted with secret key
  - “ “ bytes hashed
- **Communication Complexity:**
  - Number of message rounds
  - Bandwidth consumption
