Programming in python

BBM103 Introduction to Programming Lab 1
Week 8

Fall 2017

WHAT IS RECURSION?

- **Goal**: simplify the problem by solving the same problem for smaller input

  - Solve problems by **divide(decrease)-and-conquer**

- Function calls itself (but not infinitely!)

  - One or more base cases

ITERATION vs. RECURSION

- An **ITERATIVE** function is one that loops to repeat some part of the code.

- A **RECURSIVE** function is one that calls itself again to repeat the code.

Multiplication Example: ITERATIVE Solution

a*b is equal to "add **a** to itself **b** times"

a*b = a + a + a + a + ... + a

b times

```python
def multiply_iterative(a, b):
    result = 0
    while b > 0:
        result += a
        b -= 1
    return result
```

Iteration

Multiplication Example: RECURSIVE Solution

$$a*b = a + a + a + a + \ldots + a = \boxed{a + a*(b-1)}$$

b times

b-1 times

```
def mult_recursive(a, b):
    if b == 1:
        return a
    else:
        return a + mult_recursive(a, b-1)
```

Base case

Recursive Step

Factorial Example: ITERATIVE Solution

$$n! = n*(n-1)*(n-2)*(n-3)* \ldots * 1$$

```python
def factorial_iterative(n):
    result = 1
    while n > 0:                    ──────────→  Iteration
        result *= n
        n -= 1
    return result
```

Factorial Example: RECURSIVE Solution

$$n! = n*(n-1)*(n-2)*(n-3)* \ldots * 1$$

- **Base Case:**   if n = 1   ➡   1! = 1
- **Recursive step:**   n! = n * (n-1)!

```python
def factorial(n):
    if n == 1:                    ——→  Base case
        return 1
    else:
        return n * factorial(n-1) ——→  Recursive
                                        Step
```

ITERATION vs. RECURSION

- recursion may be simpler, more intuitive, and also efficient and natural for a programmer.

- BUT! Recursion may not be efficient from the computer's point of view.

  - Ex. Computing n^{th} Fibonacci number recursively takes $O(2^n)$ steps!

Example: Fibonacci Numbers

The Fibonacci numbers are the numbers of the following sequence of integer values:
0, 1, 1, 2, 3, 5, 8, 13, 21, 34, 55, 89, …
The Fibonacci numbers are defined by:

$F_n = F_{n-1} + F_{n-2}$
with $F_0 = 0$ and $F_1 = 1$

```python
def fibonacci(n):
    a, b = 0, 1
    for i in range(n):
        a, b = b, a + b
    return a
number=input("Please enter a number to print fibonacci numbers!")
print(fibonacci(int(number)))
```

Output:
Please enter a number to print fibonacci numbers!4
3

Example: Visualizing Recursion

```python
34 import turtle
35
36 def tree(branchLen,t):
37     if branchLen > 5:
38         t.forward(branchLen)
39         t.right(20)
40         tree(branchLen-15,t)
41         t.left(40)
42         tree(branchLen-15,t)
43         t.right(20)
44         t.backward(branchLen)
45
46 def main():
47     t = turtle.Turtle()
48     myWin = turtle.Screen()
49     t.left(90)
50     t.up()
51     t.backward(100)
52     t.down()
53     t.color("green")
54     tree(75,t)
55     myWin.exitonclick()
56
57 main()
```

Output:
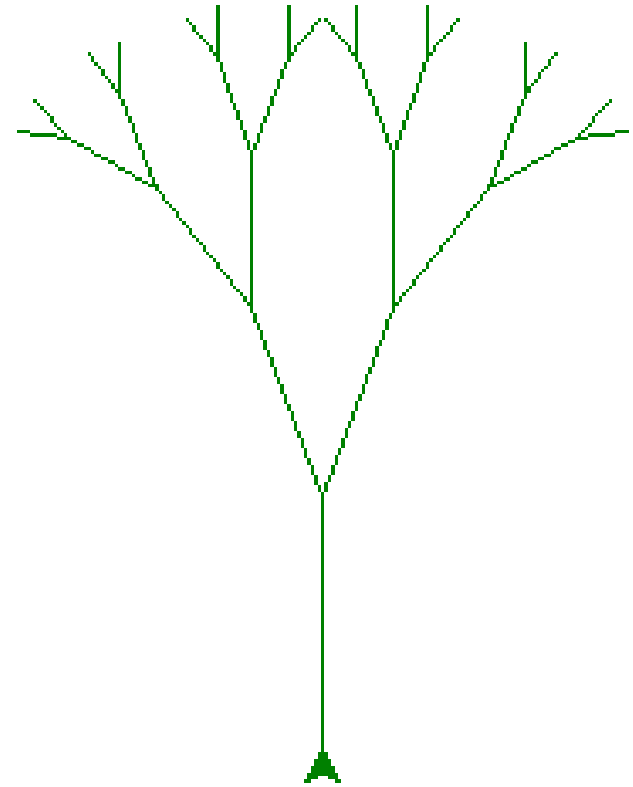

Example: Computing Exponent

```python
 9 def exp(x, n):
10     """
11     Computes the result of x raised to the power of n.
12
13         >>> exp(2, 3)
14         8
15         >>> exp(3, 2)
16         9
17     """
18     if n == 0:
19         return 1
20     else:
21         return x * exp(x, n-1)
22
23 number1=input("print a number as base")
24 number2=input("print a number as exponent")
25 print(exp(int(number1),int(number2)))
```

Lets look at the execution pattern.

```
exp(2, 4)
+-- 2 * exp(2, 3)
|         +-- 2 * exp(2, 2)
|         |         +-- 2 * exp(2, 1)
|         |         |         +-- 2 * exp(2, 0)
|         |         |         |         +-- 1
|         |         |         +-- 2 * 1
|         |         |         +-- 2
|         |         +-- 2 * 2
|         |         +-- 4
|         +-- 2 * 4
|         +-- 8
+-- 2 * 8
+-- 16
```

We can compute exponent in fewer steps if we use successive squaring.

```python
25 def fast_exp(x, n):
26     if n == 0:
27         return 1
28     elif n % 2 == 0:
29         return fast_exp(x*x, n/2)
30     else:
31         return x * fast_exp(x, n-1)
32
33 number1=input("print a number as base")
34 number2=input("print a number as exponent")
35 print(fast_exp(int(number1),int(number2)))
36
```

Lets look at the execution pattern now.

```
fast_exp(2, 10)
+-- fast_exp(4, 5) # 2 * 2
|    +-- 4 * fast_exp(4, 4)
|    |         +-- fast_exp(16, 2) # 4 * 4
|    |         |    +-- fast_exp(256, 1) # 16 * 16
|    |         |    |    +-- 256 * fast_exp(256, 0)
|    |         |    |              +-- 1
|    |         |    |    +-- 256 * 1
|    |         |    |    +-- 256
|    |         |    +-- 256
|    |         +-- 256
|    +-- 4 * 256
|    +-- 1024
+-- 1024
1024
```

Example: Flatten a List

```python
39 def flatten_list(a, result=None):
40     if result is None:
41         result = []
42
43     for x in a:
44         if isinstance(x, list):
45             flatten_list(x, result)
46         else:
47             result.append(x)
48
49     return result
50 listToFlat=[ [1, 2, [3, 4] ], [5, 6], 7]
51 print(listToFlat)
52 faltList=flatten_list(listToFlat)
53 print(faltList)
54
```

Output:
```
[[1, 2, [3, 4]], [5, 6], 7]
[1, 2, 3, 4, 5, 6, 7]
```
