BBM 101
Introduction to Programming I

Lecture #02 – Computers

John von Neumann in front of the IAS machine (1952)
Last time... What is computation

Computer science is about logic, problem solving, and creativity

**Fixed Program Computers**
- Abacus
- Antikythera Mechanism
- Pascaline
- Leibniz Wheel
- Jacquard’s Loom
- Babbage Difference Engine
- The Hollerith Electric Tabulating System
- Atanasoff-Berry Computer (ABC)
- Turing Bombe

**Declarative knowledge**
- Axioms (definitions)
- Statements of fact

**Imperative knowledge**
- How to do something
- A sequence of specific instructions (what computation is about)

**Stored Program Computers**
- Problem solving
  - What if input is a machine (description) itself?
  - Universal Turing machines
    - An abstract general purpose computer

Building a Computer

- Numbers
- Letters and Strings
- Structured Information
- Boolean Algebra and Functions
- Logic Using Electrical Circuits
- Computing With Logic
- Memory
- von Neumann Architecture
Numbers

- At the most fundamental level, a computer manipulates electricity according to specific rules.
- To make those rules produce something useful, we need to associate the electrical signals with the numbers and symbols that we, as humans, like to use.
- To represent integers, computers use combinations of numbers that are powers of 2, called the base 2 or **binary representation**
  - **bit** = 0 or 1
    - False or True
    - Off or On
    - Low voltage or High voltage

Image from: R.E. Bryant, D.R. O’Hallaron, G. Kesden
Numbers

• With four consecutive powers $2^0, 2^1, 2^2, 2^3$, we can make all of the integers from 0 to 15 using 0 or 1 of each of the four powers.

• For example, $13_{10} = 1 \cdot 2^3 + 1 \cdot 2^2 + 0 \cdot 2^1 + 1 \cdot 2^0 = 1101_2$; in other words, 1101 in base 2 means $1101_2 = 1 \cdot 2^3 + 1 \cdot 2^2 + 0 \cdot 2^1 + 1 \cdot 2^0 = 13_{10}$.

• Analogously, 603 in base 10 means $603_{10} = 6 \cdot 10^2 + 0 \cdot 10^1 + 3 \cdot 10^0$ and 207 in base 8 means $207_8 = 2 \cdot 8^2 + 0 \cdot 8^1 + 7 \cdot 8^0 = 135_{10}$.

• In general, if we choose some base $b \geq 2$, every positive integer between 0 and $b^d - 1$ can be uniquely represented using $d$ digits, with coefficients having values 0 through $b-1$.

• A modern 64-bit computer can represent integers up to $2^{64} - 1$. 
Numbers

• Arithmetic in any base is analogous to arithmetic in base 10

• Examples of addition in base 10 and base 2

\[
\begin{array}{c c c}
1 & 1 & 7 \\
1 & 7 & \\
+ & 2 & 5 \\
\hline
4 & 2 & \\
\end{array}
\quad
\begin{array}{c c c c}
1 & 1 & \text{ } & 1 \\
1 & 1 & 1 & 1 \\
+ & 1 & 1 & 0 \\
\hline
1 & 1 & 0 & 1 \\
\end{array}
\]

• To represent a negative integer, a computer typically uses a system called two’s complement, which involves flipping the bits of the positive number and then adding 1

• For example, on an 8-bit computer, 3 = 00000011, so –3 = 11111101
Numbers

- If we are using base 10 and only have eight digits to represent our numbers, we might use the first six digits for the **fractional part** of a number and last two for the **exponent**
- For example, 31415901 would represent $0.314159 \times 10^{1} = 3.14159$
- Computers use a similar idea to represent fractional numbers

IEEE 754 Floating Point Standard

\[
\begin{array}{ccc}
\text{s} & \text{e=exponent} & \text{m=mantissa} \\
1 \text{ bit} & 8 \text{ bits} & 23 \text{ bits} \\
\end{array}
\]

\[
\text{number} = (-1)^{s} \times (1.m) \times 2^{e-127}
\]
Letters and Strings

• In order to represent letters numerically, we need a convention on the encoding

• The American National Standards Institute (ANSI) has established such a convention, called ASCII (American Standard Code for Information Interchange)

• ASCII defines encodings for the upper- and lower-case letters, numbers, and a selected set of special characters

• ASCII, being an 8-bit code, can only represent 256 different symbols, and does not provide for characters used in many languages
Letters and Strings

• The International Standards Organization’s (ISO) 16-bit Unicode system can represent every character in every known language, with room for more

• Unicode being somewhat wasteful of space for English documents, ISO also defined several “Unicode Transformation Formats” (UTF), the most popular being UTF-8

<table>
<thead>
<tr>
<th>Character</th>

- Full Emoji List, v5.0
  [https://unicode.org/emoji/charts/full-emoji-list.html](https://unicode.org/emoji/charts/full-emoji-list.html)
Letters and Strings

• A string is represented as a sequence of numbers, with a “length field” at the very beginning that specifies the length of the string

• For example, in ASCII the sequence 99, 104, 111, 99, 111, 108, 97, 116, 101 translates to the string “chocolate”, with the length field set to 9
Structured Information

• We can represent any information as a sequence of numbers

• Examples
  – A picture can be represented as a sequence of pixels, each represented as three numbers giving the amount of red, green, and blue at that pixel
  – A sound can be represented as a temporal sequence of “sound pressure levels” in the air
  – A movie can be represented as a temporal sequence of individual pictures, usually 24 or 30 per second, along with a matching sound sequence
Boolean Algebra and Functions

- Boolean variables are variables that take the value True (1) or False (0)

- With Booleans 1 and 0 we could use the operations (functions) AND, OR, and NOT to build up more interesting Boolean functions

- A truth table for a Boolean function is a listing of all possible combinations of values of the input variables, together with the result produced by the function

- Truth tables for AND, OR, and NOT functions

<table>
<thead>
<tr>
<th>x</th>
<th>y</th>
<th>x AND y</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>0</td>

<td>0</td>
</tr>
</tbody>
</table>

George Boole, 1815-1864
Mathematician
Boolean Algebra and Functions

• Any function of Boolean variables, no matter how complex, can be expressed in terms of \textbf{AND}, \textbf{OR}, and \textbf{NOT}.

• Consider the proposition “if you score over 93% in both midterm and final exams, then you will get an A”.

• The truth values for the above proposition is given by the “implication” function \(( x \implies y )\) having the following truth table:

<table>
<thead>
<tr>
<th>( x )</th>
<th>( y )</th>
<th>( x \implies y )</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>0</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>1</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>1</td>
</tr>
</tbody>
</table>

• The function can be compactly written as \( \neg x \text{ OR } x \text{ AND } y \) (or \( \bar{x} + xy \)).
Boolean Algebra and Functions

- The minterm expansion algorithm, due to Claude Shannon, provides a systematic approach for building Boolean functions from truth tables

- Minterm expansion algorithm

  1. Write down the truth table for the Boolean function under consideration
  2. Delete all rows from the truth table where the value of the function is 0
  3. For each remaining row, create something called a “minterm” as follows
     - For each variable that has a 1 in that row, write the name of the variable. If the input variable is 0 in that row, write the variable with a negation symbol to NOT it
     - Now AND all of these variables together
  4. Combine all of the minterms for the rows using OR
Boolean Algebra and Functions

• For the implication function, the minterm expansion algorithm applied as follows

<table>
<thead>
<tr>
<th>x</th>
<th>y</th>
<th>$x \implies y$</th>
<th>minterm</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>1</td>
<td>$\bar{x}y$</td>
</tr>
<tr>
<td>0</td>
<td>1</td>
<td>1</td>
<td>$\bar{x}y$</td>
</tr>
<tr>
<td>1</td>
<td>0</td>
<td>0</td>
<td>$\bar{x}$</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>1</td>
<td>$xy$</td>
</tr>
</tbody>
</table>

produces the Boolean function $\bar{x}y + \bar{x}y + xy$, which is equivalent to the simpler function $\bar{x} + xy$

• Finding the simplest form of a Boolean function is provably as hard as some of the hardest (unsolved) problems in mathematics and computer science
Logic using Electrical Circuits

• An electromechanical switch in which when the input is off, the output is “low” (0), and when the input is on, the output is “high” (1)

• The NOT gate constructed using a switch that conducts only when the input is off

• The AND and OR gates for computing $x \text{ AND } y$ and $x \text{ OR } y$, constructed using electromechanical switches
Logic using Electrical Circuits

- Computers today are built with much smaller, much faster, more reliable, and more efficient transistorized switches.

- Since the details of the switches are not really important at this level of abstraction, we represent, or “abstract”, the gates using the following symbols:

  - AND
  - OR
  - NOT

- A logical circuit for the implication function $\bar{x}y + \bar{y}x + xy$.

\[
\begin{align*}
x & \\
y & \\
\text{AND} & \\
\text{OR} & \\
\text{NOT} & \\
x \Rightarrow y &
\end{align*}
\]
Computing with Logic

• A truth table describing the addition of two two-bit numbers to get a three-bit result

<table>
<thead>
<tr>
<th>x</th>
<th>y</th>
<th>x + y</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>00</td>
<td>000</td>
</tr>
<tr>
<td>00</td>
<td>01</td>
<td>001</td>
</tr>
<tr>
<td>00</td>
<td>10</td>
<td>010</td>
</tr>
<tr>
<td>.</td>
<td>.</td>
<td>.</td>
</tr>
<tr>
<td>01</td>
<td>10</td>
<td>011</td>
</tr>
<tr>
<td>01</td>
<td>11</td>
<td>100</td>
</tr>
<tr>
<td>.</td>
<td>.</td>
<td>.</td>
</tr>
<tr>
<td>11</td>
<td>11</td>
<td>110</td>
</tr>
</tbody>
</table>

• Building a corresponding circuit using the minterm expansion algorithm is infeasible — adding two 16-bit numbers, for example, will result in a circuit with several billion gates
Computing with Logic

- We build a relatively simple circuit called a full adder (FA) that does just one column of addition

\[
\begin{align*}
\text{FA} & \quad \begin{array}{c|c|c|c|c}
 x & y & c_{in} & z & c_{out} \\
\hline
 0 & 0 & 0 & 0 & 0 \\
 0 & 0 & 1 & 1 & 0 \\
 0 & 1 & 0 & 1 & 0 \\
 0 & 1 & 1 & 0 & 1 \\
 1 & 0 & 0 & 1 & 0 \\
 1 & 0 & 1 & 0 & 1 \\
 1 & 1 & 0 & 0 & 1 \\
 1 & 1 & 1 & 1 & 1 \\
\end{array}
\end{align*}
\]

- The minterm expansion principle applied to the truth table for the FA circuit yields the following Boolean functions

\[
z = \bar{x}y\bar{c}_{in} + \bar{x}y\bar{c}_{in} + x\bar{y}\bar{c}_{in} + xy\bar{c}_{in}
\]

\[
c_{out} = \bar{x}yc_{in} + x\bar{y}c_{in} + xy\bar{c}_{in} + xyc_{in}
\]
Computing with Logic

• We can “chain” $n$ full adders together to add two $n$-bit numbers, and the resulting circuit is called a ripple-carry adder.

• A 2-bit ripple-carry adder
Memory

• Truth table for a NOR gate (OR followed by NOT)

<table>
<thead>
<tr>
<th>$x$</th>
<th>$y$</th>
<th>$x \text{ NOR } y$</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>0</td>
<td>1</td>
<td>0</td>
</tr>
<tr>
<td>1</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>0</td>
</tr>
</tbody>
</table>

• A latch is a device that allows us to “lock” a bit and retrieve it later
• By aggregating millions of latches we have the Random Access Memory (RAM)
• A latch can be constructed from two NOR gates as shown below

where the input $S$ is known as “set” while the input $R$ is known as “reset”. Thus, called the SR Latch
Recall: Stored Program Concept

• Stored-program concept is the fundamental principle of the ENIAC’s successor, the EDVAC (Electronic Discrete Variable Automatic Computer)

• Instructions were stored in memory sequentially with their data

• Instructions were executed sequentially except where a conditional instruction would cause a jump to an instruction some place other than the next instruction
Stored Program Concept

• Mauchly and Eckert are generally credited with the idea of the stored-program

• BUT: John von Neumann publishes a draft report that describes the concept and earns the recognition as the inventor of the concept
  – “von Neumann architecture”
  – A First Draft of a Report of the EDVAC published in 1945
Stored Program Concept

• “Fetch-Decode-Execute” cycle
Stored Program Concept

• “Fetch-Decode-Execute” cycle

Central Processing Unit (CPU)
• In a modern computer, the CPU is where all the computation takes place
• The CPU has devices such as ripple-carry adders, multipliers, etc. for doing arithmetic. In addition, it has a small amount of (scratch) memory called registers
• The computer’s main memory, which allows storing large amounts of data, is separate from the CPU and is connected to it by wires on the computer’s circuit board
Stored Program Concept

• “Fetch-Decode-Execute” cycle

Central Processing Unit (CPU)
- ALU + Control = Processor
- Registers. Storage cells that holds heavily used program data
- Without address, specific purpose
  - e.g. the operands of an arithmetic operation, the result of an operation, etc.
Stored Program Concept

• “Fetch-Decode-Execute” cycle

BUS
- A bus is a collection of parallel wires that carry address, data, and control signals.
- Buses are typically shared by multiple devices.
Stored Program Concept

• “Fetch-Decode-Execute” cycle

Memory

• A program, which is usually a long list of instructions, is stored in the main memory, and is copied, one instruction at a time, into a register in the CPU for execution

• The CPU has two special registers: a program counter that keeps track of the location in memory where it will find the next instruction and an instruction register that stores the next instruction to execute

Central Processing Unit

Input

Arithmetic Logic Unit

Registers

Memory
Stored Program Concept

- “Fetch-Decode-Execute” cycle

![Diagram showing the relationship between Input, Central Processing Unit, Memory, Arithmetic Logic Unit, and Registers.]

**Memory**
- Instructions, like data, can be encoded as numbers

<table>
<thead>
<tr>
<th>Address</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>200</td>
<td>1000 0001 (ADD to R1)</td>

</tr>
<tr>
<td>202</td>
<td>1001 0001 (ADD to R1)</td>
</tr>
<tr>
<td>203</td>
<td>0110 0110 (data at address 102)</td>
</tr>
<tr>
<td>204</td>
<td>1111 0111 (JUMP 7 bytes)</td>
</tr>
</tbody>
</table>
von Neumann Architecture

- Let’s assume an 8-bit computer with only four instructions:
  - add, subtract, multiply, and divide
- Each of the instructions will need a number, which is called an operation code (or opcode), to represent it.
- Next, let’s assume that our computer has four registers, numbered 0 through 3, and 256 8-bit memory cells.
- An instruction will be encoded as: the first two bits represent the instruction, the next two bits encode the “destination register”, the next four bits encode the registers containing two operands.
- For example, the instruction `add 3 0 2` (meaning add the contents of register 2 with the contents of register 0 and store the result in register 3) will be encoded as `00110010`.

<table>
<thead>
<tr>
<th>Opcode</th>

<td>Divide</td>
</tr>
</tbody>
</table>
von Neumann Architecture

- Our computer operates by repeatedly performing the following procedure:
  1. Send the address in the program counter (commonly called the PC) to the memory, asking it to read that location.
  2. Load the value from memory into the instruction register.
  3. Decode the instruction register to determine what instruction to execute and which registers to use.
  4. Execute the requested instruction, which involves reading operands from registers, performing arithmetic, and sending the results back to the destination register.
  5. Increment PC so that it contains the address of the next instruction in memory.

| Program Counter | 00000000 |
| Program Counter | 00100001 |
| Instruction Register | 00000101 |

| ... | ... | ... |
| 11111111 | 255 | ... |

Central Processing Unit (CPU)    Memory
Assembly Language

• A low-level programming language for computers

• More readable, English-like abbreviations for instructions

• Architecture-specific

• Example:

  MOV AL, 61h
  MOV AX, BX
  ADD EAX, 10
  XOR EAX, EAX
Summary: Components of a Computer

- Sequential execution of machine instructions
  - The sequence of instructions are stored in the memory.
  - One instruction at a time is fetched from the memory to the control unit.
    - They are read in and treated just like data.

- PC (program counter) is responsible for the flow of control.

- PC points at a memory location containing the instruction being executed at the current time.

- Early programmers (coders) write programs via machine instructions.
Lecture Overview

• Building a Computer

• The Harvey Mudd Miniature Machine (HMMM)
The Harvey Mudd Miniature Machine (HMMM)

- HMMM
- A Simple HMMM Program
- Looping
- Functions
- HMMM Instruction Set
HMMM

• A real computer must be able to
  – Move information between registers and memory
  – Get data from the outside world
  – Print results
  – Make decisions

• The Harvey Mudd Miniature Machine (HMMM) is organized as follows
  – Both instructions and data are 16 bit wide
  – In addition to the program counter and instruction register, there are 16 registers
    named \( r_0 \) through \( r_{15} \)
  – There are 256 memory locations

• Instead of programming in binary (0’s and 1’s), we’ll use assembly language, a
  programming language where each instruction has a symbolic representation

• For example, to compute \( r_3 = r_1 + r_2 \), we will write \texttt{add r3 r1 r2}

• We will use a program to convert the assembly language into 0’s and 1’s – the
  machine language – that the computer can execute

1 \url{http://shickey.github.io/HMMM.js}
A Simple HMMM Program

Looping

- **Conditional jump** \((\text{jeqzn } rX N)\): if \(rX == 0\), then jump to line \(N\)

```plaintext
triangle3.hmmm: Calculate the approximate areas of many triangles. Stop when a base or height of zero is given.

0  read  r1     # Get base b
1  jeqzn r1 9   # Jump to halt if base is zero
2  read  r2     # Get height h
3  jeqzn r2 9   # Jump to halt if height is zero
4  mul  r1 r1 r2 # b times h into r1
5  setn r2 2
6  div  r1 r1 r2 # Divide by 2
7  write r1
8  jumpn 0
9  halt
```

Simulate!
is_it_a_prime_number.hmmm: Calculate whether a given positive number is prime or not

0    read r1          # read the number. Please enter positive integers.
1    setn r2 2        # use this register for arithmetic operations with 2.
2    setn r9 1        # use this register for arithmetic operations with 1.
3    sub r15 r1 r9
4    jeqzn r15 17     # check if the number is 1
5    div r3 r1 r2     # Divide to 2. The biggest divider (denominator) should (may) be this number.
6    # there is no reason. Deleted a line, but too lazy to change all the line numbers.
7    sub r15 r3 r9
8    jeqz r15 15      # the number is 2 or 3. So it is prime.
9    mod r15 r1 r3    # mod to check if the number is aliquot.
10   jeqzn r15 17     # it is not a prime number. Jump to line 17.
11   sub r3 r3 r9     # subtract one from the divider
12   sub r5 r3 r9     # subtract one, but on a different register to check the divider is 1 or not.
13   jeqz r5 15       # we succesfully reduced the divider to 1. This is a prime number. Jump to line 15.
14   jumpn 9          # jump to the start of the main loop.

# The number is not 1, 2 or 3. The main loop starts here------------------------
15   write r9         # r9 is already 1.
16   halt

#---------------------------------- Write 0 for non-prime numbers.
17   setn r8 0
18   write r8
19   halt
Functions

- **Call a function** \((\text{calln } rX \ N)\): copy the next address (aka return address) into \(rX\) and then jump to address \(N\)

- **Return from a function** \((\text{jumpr } rX)\): set program counter to the return address in \(rX\)

- By convention, we use register \(r14\) to store the return address

```plaintext
square.hmmm: Calculate the square of a number \(N\).

0     read     r1    # Get N
1    calln     r14    5    # Calculate \(N^2\)
2    write     r2    # Write answer
3    halt
4    \# Write answer

# Square function. \(N\) is in r1. Result \((N^2)\) is in r2. Return address is in r14.
5    \# Calculate and store \(N^2\) in r2
6    jumpr     r14    # Done; return to caller
```

11
121
Functions

combinations.hmmm: Calculate \( C(N, K) \) (aka \( N \) choose \( K \)) defined as \( C(N, K) = N!/(K!(N - K)!) \), where \( N! \) (\( N \) factorial) is defined as \( N! = N \times (N - 1) \times (N - 2) \times \cdots \times 2 \times 1 \), with \( 0! = 1 \).

0  read   r3      # Get N
1  read   r4      # Get K
2  copy   r1 r3   # Calculate N!
3  calln  r14 15  # ...
4  copy   r5 r2   # Save N! as C(N, K)
5  copy   r1 r4   # Calculate K!
6  calln  r14 15  # ...
7  div    r5 r5 r2 # N!/K!
8  sub    r1 r3 r4 # Calculate (N - K)!
9  calln  r14 15  # ...
10  div    r5 r5 r2 # C(N, K)
11  write  r5      # Write answer
12  halt
13  nop    # Waste some space
14  nop

# Factorial function. N is in r1. Result is r2. Return address is in r14.
15  setn   r2 1    # Initial product
16  jeqzn  r1 20   # Quit if N has reached zero
17  mulzn  r2 r1 r2 # Update product
18  addn   r1 -1   # Decrement N
19  jumpn  16      # Back for more
20  jumpn  r14     # Done; return to caller

</table>
HMMM Instruction Set

• **System instructions**

  - `halt`
  - `stop`
  - `read rX` place user input in register `rX`
  - `write rX` print contents of register `rX`
  - `nop` do nothing

• **Setting register data**

  - `setn rX N` set register `rX` equal to the integer `N` (-128 to 127)
  - `addn rX N` add integer `N` (-128 to 127) to register `rX`
  - `copy rX rY` set `rX=rY`

• **Arithmetic**

  - `add rX rY rZ` set `rX=rY+rZ`
  - `sub rX rY rZ` set `rX=rY-rZ`
  - `neg rX rY` set `rX=-rY`
  - `mul rX rY rZ` set `rX=rY*rZ`
  - `div rX rY rZ` set `rX=rY/rZ` (integer division; no remainder)
  - `mod rX rY rZ` set `rX=rY%rZ` (returns the remainder of integer division)
HMMM Instruction Set

- **Jumps**
  - `jumpn N` set program counter to address \( N \)
  - `jumpr rX` set program counter to address in \( rX \)
  - `jeqzn rX N` if \( rX=0 \), then jump to line \( N \)
  - `jnezn rX N` if \( rX\neq0 \), then jump to line \( N \)
  - `jgtzn rX N` if \( rX>0 \), then jump to line \( N \)
  - `jltzn rX N` if \( rX<0 \), then jump to line \( N \)
  - `calln rX N` copy the next address into \( rX \) and then jump to address \( N \)

- **Interacting with memory**
  - `loadn rX N` load register \( rX \) with the contents of address \( N \)
  - `storen rX N` store contents of register \( rX \) into address \( N \)
  - `loadr rX rY` load register \( rX \) with data from the address location held in register \( rY \)
  - `storer rX rY` store contents of register \( rX \) into address held in register \( rY \)
