- Boyer-Moore
- Rabin-Karp
Substring search

Goal. Find pattern of length $M$ in a text of length $N$.

Typically $N \gg M$

**pattern** $\rightarrow$ NEEDLE

**text** $\rightarrow$ INAHAYSTACK NEEDLE INA

match
Substring search applications

Goal. Find pattern of length $M$ in a text of length $N$.

Computer forensics. Search memory or disk for signatures, e.g., all URLs or RSA keys that the user has entered.
Substring search applications

Goal. Find pattern of length $M$ in a text of length $N.$

- Typically $N \gg M$

Identify patterns indicative of spam.

- PROFITS
- LOSE WEIGHT
- There is no catch.
- This is a one-time mailing.
- This message is sent in compliance with spam regulations.
Substring search applications

Electronic surveillance.

Need to monitor all internet traffic.

(security)

No way!

(privacy)

Well, we’re mainly interested in “ATTACK AT DAWN”

OK. Build a machine that just looks for that.

“ATTACK AT DAWN” substring search machine found
Substring search applications

Screen scraping. Extract relevant data from web page.

Ex. Find string delimited by `<b>` and `</b>` after first occurrence of pattern Last Trade:

```
http://finance.yahoo.com/q?s=goog
```

...<tr>
<td class="yfnc_tablehead1" width="48">
Last Trade: </td>
<td class="yfnc_tabledata1">
452.92 </td>
</tr>
<td class="yfnc_tablehead1" width="48">
Trade Time: </td>
<td class="yfnc_tabledata1">
...
Screen scraping: Java implementation

Java library. The `indexOf()` method in Java's string library returns the index of the first occurrence of a given string, starting at a given offset.

```java
public class StockQuote {
    public static void main(String[] args) {
        String name = "http://finance.yahoo.com/q?s=",
        In in = new In(name + args[0]);
        String text = in.readAll();
        int start = text.indexOf("Last Trade:", 0);
        int from = text.indexOf("<b>", start);
        int to = text.indexOf("</b>", from);
        String price = text.substring(from + 3, to);
        StdOut.println(price);
    }
}
```

% java StockQuote goog
582.93

% java StockQuote msft
24.84
Substring Search

Worst case. \( \sim MN \) char compares.
In many applications, we want to avoid backup in text stream.
- Treat input as stream of data.
- Abstract model: standard input.

Brute-force algorithm needs backup for every mismatch.

Approach 1. Maintain buffer of last $M$ characters.
Approach 2. Stay tuned.
Brute-force substring search: alternate implementation

Same sequence of char compares as previous implementation.

- i points to end of sequence of already-matched chars in text.
- j stores number of already-matched chars (end of sequence in pattern).

```
public static int search(String pat, String txt)
{
    int i, N = txt.length();
    int j, M = pat.length();
    for (i = 0, j = 0; i < N && j < M; i++)
    {
        if (txt.charAt(i) == pat.charAt(j)) j++;
        else { i -= j; j = 0; }  // backup
    }
    if (j == M) return i - M;
    else            return N;
}
```
Algorithmic challenges in substring search

Brute-force is not always good enough.

Theoretical challenge. Linear-time guarantee. ← fundamental algorithmic problem

Practical challenge. Avoid backup in text stream. ← often no room or time to save text

Now is the time for all people to come to the aid of their party. Now is the time for all good people to come to the aid of their party. Now is the time for many good people to come to the aid of their party. Now is the time for all good people to come to the aid of their party. Now is the time for a lot of good people to come to the aid of their party. Now is the time for all of the good people to come to the aid of their party. Now is the time for all good people to come to the aid of their party. Now is the time for each good person to come to the aid of their party. Now is the time for all good people to come to the aid of their party. Now is the time for all good Republicans to come to the aid of their party. Now is the time for all good Democrats to come to the aid of their party. Now is the time for all good people to come to the aid of their party. Now is the time for many good people to come to the aid of their party. Now is the time for all good people to come to the aid of their party. Now is the time for all good people to come to the aid of their party. Now is the time for a lot of good people to come to the aid of their party. Now is the time for each person to come to the aid of their party. Now is the time for all good people to come to the aid of their party. Now is the time for all good Republicans to come to the aid of their party. Now is the time for all good people to come to the aid of their party. Now is the time for many or all good people to come to the aid of their party. Now is the time for all good people to come to the aid of their party. Now is the time for all good Democrats to come to the aid of their party.
Substring Search

- Brute force
- Knuth-Morris-Pratt
- Boyer-Moore
- Rabin-Karp
Knuth-Morris-Pratt substring search

Intuition. Suppose we are searching in text for pattern \texttt{BAAAAAAAA}.  
• Suppose we match 5 chars in pattern, with mismatch on 6\textsuperscript{th} char.  
• We know previous 6 chars in text are \texttt{BAAAAB}.  
• Don’t need to back up text pointer!

Knuth-Morris-Pratt algorithm. Clever method to always avoid backup. (!)
Deterministic finite state automaton (DFA)

DFA is abstract string-searching machine.
- Finite number of states (including start and halt).
- Exactly one transition for each char in alphabet.
- Accept if sequence of transitions leads to halt state.

substring found
Q. What is interpretation of DFA state after reading in $\text{txt}[i]$?
A. State = number of characters in pattern that have been matched.

Ex. DFA is in state 3 after reading in $\text{txt}[0..6]$.

$\text{txt}$ $\text{pat}$

prefix of pat[]

length of longest prefix of pat[] that is a suffix of txt[0..i]
Knuth-Morris-Pratt substring search: Java implementation

Key differences from brute-force implementation.

- Need to precompute $dfa[][]$ from pattern.
- Text pointer $i$ never decrements.

```java
public int search(String txt) {
    int i, j, N = txt.length();
    for (i = 0, j = 0; i < N && j < M; i++)
        j = dfa[txt.charAt(i)][j];
    if (j == M) return i - M;
    else return N;
}
```

Running time.

- Simulate DFA on text: at most $N$ character accesses.
- Build DFA: how to do efficiently? [warning: tricky algorithm ahead]
Knuth-Morris-Pratt substring search: Java implementation

Key differences from brute-force implementation.
- Need to precompute $dfa[][]$ from pattern.
- Text pointer $i$ never decrements.
- Could use input stream.

```java
public int search(In in)
{
    int i, j;
    for (i = 0, j = 0; !in.isEmpty() && j < M; i++)
        j = dfa[in.readChar()][j];
    if (j == M) return i - M;
    else return NOT_FOUND;
}
```

Constructing the DFA for KMP substring search for A B A B A C

How to build DFA from pattern?

Mismatch transition. If in state $j$ and next char $c \neq \text{pat.charAt}(j)$, then the last $j-1$ characters of input are $\text{pat}[1..j-1]$, followed by $c$.

To compute $\text{dfa}[c][j]$: Simulate $\text{pat}[1..j-1]$ on DFA and take transition $c$.

Running time. Seems to require $j$ steps.

**Ex.** $\text{dfa['A'][5]} = 1$; $\text{dfa['B'][5]} = 4$

simulate BABA; simulate BABA; 
take transition 'A' take transition 'B' 
= $\text{dfa['A'][3]}$ = $\text{dfa['B'][3]}$

Constructing the DFA for KMP substring search for A B A B A C
Constructing the DFA for KMP substring search: Java implementation

For each state $j$:

- Copy $\text{dfa}[X]$ to $\text{dfa}[j]$ for mismatch case.
- Set $\text{dfa}[$pat.charAt($j$)][j]$ to $j+1$ for match case.
- Update $X$.

```java
public KMP(String pat) {
    this.pat = pat;
    M = pat.length();
    dfa = new int[R][M];
    dfa[pat.charAt(0)][0] = 1;
    for (int X = 0, j = 1; j < M; j++) {
        for (int c = 0; c < R; c++)
            dfa[c][j] = dfa[c][X];  // copy mismatch cases
        dfa[pat.charAt(j)][j] = j+1;  // set match case
        X = dfa[pat.charAt(j)][X];  // update restart state
    }
}
```

Running time. $M$ character accesses (but space proportional to $RM$).
KMP substring search analysis

Proposition. KMP substring search accesses no more than $M + N$ chars to search for a pattern of length $M$ in a text of length $N$.

Pf. Each pattern char accessed once when constructing the DFA; each text char accessed once (in the worst case) when simulating the DFA.

Proposition. KMP constructs $\text{dfa}[][]$ in time and space proportional to $RM$.

Larger alphabets. Improved version of KMP constructs $\text{nfa}[]$ in time and space proportional to $M$.

![KMP NFA for ABABAC]
Knuth-Morris-Pratt: brief history

• Independently discovered by two theoreticians and a hacker.
  - Knuth: inspired by esoteric theorem, discovered linear-time algorithm
  - Pratt: made running time independent of alphabet size
  - Morris: built a text editor for the CDC 6400 computer

• Theory meets practice.

SIAM J. COMPUT.
Vol. 6, No. 2, June 1977

FAST PATTERN MATCHING IN STRINGS*

DONALD E. KNUTH†, JAMES H. MORRIS, JR.‡ AND VAUGHAN R. PRATT§

Abstract. An algorithm is presented which finds all occurrences of one given string within another, in running time proportional to the sum of the lengths of the strings. The constant of proportionality is low enough to make this algorithm of practical use, and the procedure can also be extended to deal with some more general pattern-matching problems. A theoretical application of the algorithm shows that the set of concatenations of even palindromes, i.e., the language \( \{aa^n\}^* \), can be recognized in linear time. Other algorithms which run even faster on the average are also considered.

Don Knuth  Jim Morris  Vaughan Pratt
**Substring Search**

- Brute force
- Knuth-Morris-Pratt
- Boyer-Moore
- Rabin-Karp
Boyer Moore Intuition

• Scan the text with a window of M chars (length of pattern)

  Pattern in Text (M)

<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Text</td>
</tr>
</tbody>
</table>

| Scan Window (M)    |

• Case 1: Scan Window is exactly on top of the searched pattern

  - Starting from one end check if all characters are equal. (We must check!)

• Case 2: Scan Window starts after the pattern starts.
Boyer Moore Intuition (2)

- Case 3: Scan Window starts before the pattern starts

- Case 4: Independent

- In case 4, simply shift window M characters
- Avoid Case 2
- Convert Case 3 to Case 1, by shifting appropriately
Boyer Moore Intuition (3)

- If we can recognise the character in the scan window end-point, we can find how many characters to shift.

- So, for example D is the 4th character, we must shift window 4 characters so that they overlap.
Boyer Moore Intuition (4)

- A potential problem, the character in the text can repeat.

- For example, pattern = XXAXX and the text is

  A X A X A X A X X A X A X A X A X

- Solution: be conservative, choose the instance with the least Shift (so we cannot miss the others).
Boyer Moore Intuition (5)

- A X A X A X X A X X A X X A X A X X A X
  Search: XXAXX
- So, for the example when it is A at the endpoint we must shift for 2 characters.
  - text: AAAAX we have a mismatch in last A, now we must shift only once, so that we can check the configuration where the A we found moves to middle.
  - text: AAYXX we have a mismatch in Y, now we must shift 3 times as we know that the last 2 characters are in pattern and they can be repeating in the first 3 characters.
Boyer-Moore: mismatched character heuristic

Intuition.
- Scan characters in pattern from right to left.
- Can skip as many as $M$ text chars when finding one not in the pattern.
  - First we check the character in index pattern.length()-1
  - It is N which is not E, so we know that first 5 characters is not a match. Shift text 5 characters
  - S != E so shift 5, E == E so we can check for the pattern.length()-2, L!=N, skip 4.

\[
\begin{array}{cccccccccccccccccccccccc}
\text{i} & \text{j} & 0 & 1 & 2 & 3 & 4 & 5 & 6 & 7 & 8 & 9 & 10 & 11 & 12 & 13 & 14 & 15 & 16 & 17 & 18 & 19 & 20 & 21 & 22 & 23 \\
\hline
0 & 5 & N & E & E & D & L & E & \leftarrow \text{pattern} \\
5 & 5 & N & E & E & D & L & E \\
11 & 4 & N & E & E & D & L & E \\
15 & 0 & N & E & E & D & L & E \\
\end{array}
\]

\text{return i = 15}
Boyer-Moore: mismatched character heuristic

Q. How much to skip?

Case 1. Mismatch character not in pattern.

Before:

before

\[
\begin{align*}
\text{txt} & \quad \ldots \ldots \cdot T L E \ldots \ldots \\
\text{pat} & \quad N E E D L E
\end{align*}
\]

After:

\[
\begin{align*}
\text{txt} & \quad \ldots \ldots \cdot T L E \ldots \ldots \\
\text{pat} & \quad N E E D L E
\end{align*}
\]

mismatch character 'T' not in pattern: increment i one character beyond 'T'
Boyer-Moore: mismatched character heuristic

Q. How much to skip?

Case 2a. Mismatch character in pattern.

mismatch character 'N' in pattern: align text 'N' with rightmost pattern 'N'
Boyer-Moore: mismatched character heuristic

Q. How much to skip?

Case 2b. Mismatch character in pattern (but heuristic no help).

before ↓

\begin{align*}
\text{txt} & \quad . \quad . \quad . \quad . \quad E \quad L \quad E \quad . \quad . \quad . \quad . \\
\text{pat} & \quad N \quad E \quad E \quad D \quad L \quad E
\end{align*}

aligned with rightmost E?

\begin{align*}
\text{txt} & \quad . \quad . \quad . \quad . \quad E \quad L \quad E \quad . \quad . \quad . \quad . \\
\text{pat} & \quad N \quad E \quad E \quad D \quad L \quad E
\end{align*}

mismatch character 'E' in pattern: align text 'E' with rightmost pattern 'E'?
Boyer-Moore: mismatched character heuristic

Q. How much to skip?

Case 2b. Mismatch character in pattern (but heuristic no help).

Mismatch character 'E' in pattern: increment i by 1
Boyer-Moore: mismatched character heuristic

Q. How much to skip?

A. Precompute index of rightmost occurrence of character $c$ in pattern (-1 if character not in pattern).

```java
right = new int[R];
for (int c = 0; c < R; c++)
    right[c] = -1;
for (int j = 0; j < M; j++)
    right[pat.charAt(j)] = j;
```

Boyer-Moore skip table computation
public int search(String txt)
{
    int N = txt.length();
    int M = pat.length();
    int skip;
    for (int i = 0; i <= N-M; i += skip)
    {
        skip = 0;
        for (int j = M-1; j >= 0; j--)
        {
            if (pat.charAt(j) != txt.charAt(i+j))
            {
                skip = Math.max(1, j - right[txt.charAt(i+j)]);
                break;
            }
        }
        if (skip == 0) return i;
    }
    return N;
}
Another Example

SEARCH FOR: XXXX

A X A X A X A X X X A X A X X X X A A A

If the window scan points to an unrecognised character, we can skip past that character. For this example, for the initial step we first match X at the end, when check for previous character (A) which is not in the string we skip 3 steps. The X at the end, we matched can still be the first character of the pattern, so we do not skip that.
Boyer-Moore: analysis

Property. Substring search with the Boyer-Moore mismatched character heuristic takes about $\sim \frac{N}{M}$ character compares to search for a pattern of length $M$ in a text of length $N$. sublinear!

Worst-case. Can be as bad as $\sim MN$.

Boyer-Moore variant. Can improve worst case to $\sim 3N$ by adding a KMP-like rule to guard against repetitive patterns.
Substring Search

- Brute force
- Knuth-Morris-Pratt
- Boyer-Moore
- Rabin-Karp
**Rabin-Karp fingerprint search**

Basic idea = modular hashing.
- Compute a hash of pattern characters 0 to $M - 1$.
- For each $i$, compute a hash of text characters $i$ to $M + i - 1$.
- If pattern hash = text substring hash, check for a match.

```
pat.charAt(i)
  i  0  1  2  3  4
  2  6  5  3  5
% 997 = 613

txt.charAt(i)
  i  0  1  2  3  4  5  6  7  8  9 10 11 12 13 14 15
  3  1  4  1  5  9  2  6  5  3  5  8  9  7  9  3
% 997 = 508
  1  1  4  1  5  9  2 % 997 = 201
  2  4  1  5  9  2 % 997 = 715
  3  1  5  9  2  6 % 997 = 971
  4  5  9  2  6  5 % 997 = 442
  5  9  2  6  5  3 % 997 = 929
  match

6 ← return i = 6
  2  6  5  3  5 % 997 = 613
```
Efficiently computing the hash function

Modular hash function. Using the notation \( t_i \) for \( \text{txt.charAt}(i) \), we wish to compute

\[ x_i = t_i R^{M-1} + t_{i+1} R^{M-2} + \ldots + t_{i+M-1} R^0 \pmod{Q} \]

Intuition. \( M \)-digit, base-\( R \) integer, modulo \( Q \).

Horner's method. Linear-time method to evaluate degree-\( M \) polynomial.

```
// Compute hash for M-digit key
private long hash(String key, int M) {  
    long h = 0;
    for (int j = 0; j < M; j++)
        h = (R * h + key.charAt(j)) % Q;
    return h;
}
```
Efficiently computing the hash function

Challenge. How to efficiently compute $x_{i+1}$ given that we know $x_i$.

- $x_i = t_i R^{M-1} + t_{i+1} R^{M-2} + ... + t_{i+M-1} R^0$
- $x_{i+1} = t_{i+1} R^{M-1} + t_{i+2} R^{M-2} + ... + t_{i+M} R^0$

Key property. Can update hash function in constant time!

- $x_{i+1} = (x_i - t_i R^{M-1}) R + t_{i+M} \uparrow \uparrow \uparrow \uparrow$
  - current value
  - subtract leading digit
  - multiply by radix
  - add new trailing digit (can precompute $R^{M-2}$)

\[ 10 \quad 2 \quad 6 \quad 5 \quad 3 \quad 5 \quad (929 + 9 \times 997 - 30) \times 10 + 5) \% 997 = 613 \]
public class RabinKarp
{
    private long patHash; // pattern hash value
    private int M; // pattern length
    private long Q; // modulus
    private int R; // radix
    private long RM; // R^(M-1) % Q

    public RabinKarp(String pat) {
        M = pat.length();
        R = 256;
        Q = longRandomPrime();
        RM = 1;
        for (int i = 1; i <= M-1; i++)
            RM = (R * RM) % Q;
        patHash = hash(pat, M);
    }

    private long hash(String key, int M) {
        /* as before */
    }

    public int search(String txt) {
        /* see next slide */
    }
}
Rabin-Karp: Java implementation (continued)

Monte Carlo version. Return match if hash match.

```java
public int search(String txt)
{
    int N = txt.length();
    int txtHash = hash(txt, M);
    if (patHash == txtHash) return 0;
    for (int i = M; i < N; i++)
    {
        txtHash = (txtHash + Q - RM*txt.charAt(i-M) % Q) % Q;
        txtHash = (txtHash*R + txt.charAt(i)) % Q;
        if (patHash == txtHash) return i - M + 1;
    }
    return N;
}
```

Las Vegas version. Check for substring match if hash match; continue search if false collision.
Rabin-Karp analysis

Theory. If $Q$ is a sufficiently large random prime (about $MN^2$), then the probability of a false collision is about $1/N$.

Practice. Choose $Q$ to be a large prime (but not so large as to cause overflow). Under reasonable assumptions, probability of a collision is about $1/Q$.

Monte Carlo version.
- Always runs in linear time.
- Extremely likely to return correct answer (but not always!).

Las Vegas version.
- Always returns correct answer.
- Extremely likely to run in linear time (but worst case is $MN$).
Rabin-Karp fingerprint search

Advantages.
• Extends to 2d patterns.
• Extends to finding multiple patterns.

Disadvantages.
• Arithmetic ops slower than char compares.
• Las Vegas version requires backup.
• Poor worst-case guarantee.
Substring search cost summary

Cost of searching for an $M$-character pattern in an $N$-character text.
