Active Contours/Snakes
Variational Segmentation Models

Fitting: Edges vs. boundaries

Edges useful signal to indicate occluding boundaries, shape.
Here the raw edge output is not so bad...

...but quite often boundaries of interest are fragmented, and we have extra “clutter” edge points.

Images from D. Jacobs
Given a model of interest, we can overcome some of the missing and noisy edges using fitting techniques.

With voting methods like the Hough transform, detected points vote on possible model parameters.

**Deformable contours**

a.k.a. active contours, snakes

**Given:** initial contour (model) near desired object

**Goal:** evolve the contour to fit exact object boundary

**Main idea:** elastic band is iteratively adjusted so as to

- be near image positions with high gradients, and
- satisfy shape “preferences” or contour priors

**Deformable contours: intuition**

**Deformable contours vs. Hough**

Like generalized Hough transform, useful for shape fitting; but

- Rigid model shape
- Single voting pass can detect multiple instances

Hough

- Prior on shape types, but shape iteratively adjusted (deforms)
- Requires initialization nearby
- One optimization “pass” to fit a single contour

Deformable contours

- Prior on shape types, but shape iteratively adjusted (deforms)
- Requires initialization nearby
- One optimization “pass” to fit a single contour
Why do we want to fit deformable shapes?

- Some objects have similar basic form but some variety in the contour shape.

Why do we want to fit deformable shapes?

- Non-rigid, deformable objects can change their shape over time.

Aspects we need to consider

- Representation of the contours
- Defining the energy functions
  - External
  - Internal
- Minimizing the energy function

Representation

- We’ll consider a discrete representation of the contour, consisting of a list of 2d point positions (“vertices”).

\[
\mathbf{V}_i = (x_i, y_i), \quad \text{for } i = 0, 1, \ldots, n - 1
\]

- At each iteration, we’ll have the option to move each vertex to another nearby location (“state”).

Figure credit: Julien Jomier
Fitting deformable contours

How should we adjust the current contour to form the new contour at each iteration?

• Define a cost function ("energy" function) that says how good a candidate configuration is.
• Seek next configuration that minimizes that cost function.

Energy function

The total energy (cost) of the current snake is defined as:

$$E_{total} = E_{internal} + E_{external}$$

Internal energy: encourage prior shape preferences: e.g., smoothness, elasticity, particular known shape.

External energy ("image" energy): encourage contour to fit on places where image structures exist, e.g., edges.

A good fit between the current deformable contour and the target shape in the image will yield a low value for this cost function.

External energy: intuition

• Measure how well the curve matches the image data
• "Attract" the curve toward different image features
  – Edges, lines, texture gradient, etc.

External image energy

How do edges affect "snap" of rubber band?

Think of external energy from image as gravitational pull towards areas of high contrast

Magnitude of gradient

$$G_x(I)^2 + G_y(I)^2$$

$- \left( G_x(I)^2 + G_y(I)^2 \right)$
External image energy

- Gradient images $G_x(x, y)$ and $G_y(x, y)$

- External energy at a point on the curve is:
  $$E_{\text{external}}(v) = -(\|G_x(v)\|^2 + \|G_y(v)\|^2)$$

- External energy for the whole curve:
  $$E_{\text{external}} = -\sum_{i=0}^{n-1} |G_x(x_i, y_i)|^2 + |G_y(x_i, y_i)|^2$$

Internal energy: intuition

A priori, we want to favor smooth shapes, contours with low curvature, contours similar to a known shape, etc. to balance what is actually observed (i.e., in the gradient image).

Internal energy: intuition

What are the underlying boundaries in this fragmented edge image?

And in this one?

Internal energy

For a continuous curve, a common internal energy term is the “bending energy”.

At some point $v(s)$ on the curve, this is:

$$E_{\text{internal}}(v(s)) = \alpha \left| \frac{d v}{d s} \right|^2 + \beta \left| \frac{d^2 v}{d s^2} \right|^2$$

- Tension, Elasticity
- Stiffness, Curvature
Internal energy

- For our discrete representation,
  \[
  \mathbf{v}_i = (x_i, y_i), \quad i = 0 \ldots n-1
  \]
  \[
  \frac{d\mathbf{v}}{ds} = \mathbf{v}_{i+1} - \mathbf{v}_i
  \]
  \[
  \frac{d^2\mathbf{v}}{ds^2} = (\mathbf{v}_{i+1} - \mathbf{v}_i) - (\mathbf{v}_i - \mathbf{v}_{i-1}) = \mathbf{v}_{i+1} - 2\mathbf{v}_i + \mathbf{v}_{i-1}
  \]

  Note these are derivatives relative to position---not spatial image gradients.

- Internal energy for the whole curve:
  \[
  E_{\text{internal}} = \sum_{i=0}^{n-1} \alpha \|\mathbf{v}_{i+1} - \mathbf{v}_i\|^2 + \beta \|\mathbf{v}_{i+1} - 2\mathbf{v}_i + \mathbf{v}_{i-1}\|^2
  \]

  Why do these reflect tension and curvature?

Example: compare curvature

\[
E_{\text{curvature}}(v_i) = \|\mathbf{v}_{i+1} - 2\mathbf{v}_i + \mathbf{v}_{i-1}\|^2
= (x_{i+1} - 2x_i + x_{i-1})^2 + (y_{i+1} - 2y_i + y_{i-1})^2
\]

Penalizing elasticity

- Current elastic energy definition uses a discrete estimate of the derivative:
  \[
  E_{\text{elastic}} = \sum_{i=0}^{n-1} \alpha \|\mathbf{v}_{i+1} - \mathbf{v}_i\|^2
  \]
  \[
  = \alpha \cdot \sum_{i=0}^{n-1} (x_{i+1} - x_i)^2 + (y_{i+1} - y_i)^2
  \]

  What is the possible problem with this definition?

Penalizing elasticity

- Current elastic energy definition uses a discrete estimate of the derivative:
  \[
  E_{\text{elastic}} = \sum_{i=0}^{n-1} \alpha \|\mathbf{v}_{i+1} - \mathbf{v}_i\|^2
  \]
  \[
  = \alpha \cdot \sum_{i=0}^{n-1} (x_{i+1} - x_i)^2 + (y_{i+1} - y_i)^2 - \bar{d}^2
  \]

  where \(\bar{d}\) is the average distance between pairs of points – updated at each iteration.
Dealing with missing data

- The preferences for low-curvature, smoothness help deal with missing data:

![Illusory contours found!](Figure from Kass et al. 1987)

Extending the internal energy: capture shape prior

- If object is some smooth variation on a known shape, we can use a term that will penalize deviation from that shape:

\[ E_{\text{internal}} + \alpha \cdot \sum_{i=0}^{n-1} (\mathbf{v}_i - \hat{\mathbf{v}}_i)^2 \]

where \( \{ \hat{\mathbf{v}}_i \} \) are the points of the known shape.

Total energy: function of the weights

\[ E_{\text{total}} = E_{\text{internal}} + \gamma E_{\text{external}} \]

\[ E_{\text{external}} = - \sum_{i=0}^{n-1} |G_x(x_i, y_i)|^2 + |G_y(x_i, y_i)|^2 \]

\[ E_{\text{internal}} = \sum_{i=0}^{n-1} \alpha (|d| - \|\mathbf{v}_{i+1} - \mathbf{v}_i\|)^2 + \beta \|\mathbf{v}_{i+1} - 2\mathbf{v}_i + \mathbf{v}_{i-1}\|^2 \]
Recap: deformable contour

- A simple elastic snake is defined by:
  - A set of \( n \) points,
  - An internal energy term (tension, bending, plus optional shape prior)
  - An external energy term (gradient-based)

- To use to segment an object:
  - Initialize in the vicinity of the object
  - Modify the points to minimize the total energy

Energy minimization

- Several algorithms have been proposed to fit deformable contours:
  - Greedy search
  - Dynamic programming (for 2D snakes)
  - etc.

Energy minimization: greedy

- For each point, search window around it and move to where energy function is minimal
  - Typical window size, e.g., 5 x 5 pixels

- Stop when predefined number of points have not changed in last iteration, or after max number of iterations

- Note:
  - Convergence not guaranteed
  - Need decent initialization

Energy minimization: dynamic programming

With this form of the energy function, we can minimize using dynamic programming, with the Viterbi algorithm.

Iterate until optimal position for each point is the center of the box, i.e., the snake is optimal in the local search space constrained by boxes.

Fig from Y. Boykov [Amini, Weymouth, Jain, 1990]
Energy minimization: dynamic programming

- Possible because snake energy can be rewritten as a sum of
  pair-wise interaction potentials:

\[
E_{\text{total}}(v_1, \ldots, v_n) = \sum_{i=1}^{n-1} E_i(v_i, v_{i+1})
\]

- Or sum of triple-interaction potentials.

\[
E_{\text{total}}(v_1, \ldots, v_n) = \sum_{i=1}^{n-1} E_i(v_{i-1}, v_i, v_{i+1})
\]

Snake energy: pair-wise interactions

\[
E_{\text{total}}(x_1, \ldots, x_n, y_1, \ldots, y_n) = -\sum_{i=1}^{n-1} |G_x(x_i, y_i)|^2 + |G_y(x_i, y_i)|^2 + \alpha \sum_{i=1}^{n-1} (x_{i+1} - x_i)^2 + (y_{i+1} - y_i)^2
\]

Re-writing the above with \((x, y)\):

\[
E_{\text{total}}(v_1, \ldots, v_n) = -\sum_{i=1}^{n-1} \|G(v_i)\|^2 + \alpha \sum_{i=1}^{n-1} \|v_{i+1} - v_i\|^2
\]

\[
E_{\text{total}}(v_1, \ldots, v_n) = E_1(v_1, v_2) + E_2(v_2, v_3) + \ldots + E_{n-1}(v_{n-1}, v_n)
\]

where \(E_i(v_i, v_{i+1}) = -\|G(v_i)\|^2 + \alpha \|v_{i+1} - v_i\|^2\)

Limitations

- May over-smooth the boundary

- Cannot follow topological changes of objects
Limitations

- External energy: snake does not really “see” object boundaries in the image unless it gets very close to it.

Distance transform

- External image can instead be taken from the distance transform of the edge image.

Deformable contours: pros and cons

**Pros:**
- Useful to track and fit non-rigid shapes
- Contour remains connected
- Possible to fill in “subjective” contours
- Flexibility in how energy function is defined, weighted.

**Cons:**
- Must have decent initialization near true boundary, may get stuck in local minimum
- Parameters of energy function must be set well based on prior information

Summary

- Deformable shapes and active contours are useful for
  - Segmentation: fit or “snap” to boundary in image
  - Tracking: previous frame’s estimate serves to initialize the next

- Fitting active contours:
  - Define terms to encourage certain shapes, smoothness, low curvature, push/pulls, …
  - Use weights to control relative influence of each component cost
  - Can optimize 2d snakes with Viterbi algorithm.

- Image structure (esp. gradients) can act as attraction force for interactive segmentation methods.
Today

- Variational Segmentation Models

Review – Nonlinear Diffusion

- use nonlinear PDEs to create a scale space representation
  - consists of gradually simplified images
  - some image features such as edges are maintained or even enhanced.
- Perona-Malik Type Nonlinear Diffusion (1990)
- Total Variation (TV) Regularization (1992)
- Weickert’s Edge Enhancing Diffusion (1994)

Review - Perona-Malik Type Nonlinear Diffusion

- Perona-Malik equation is:
  \[
  \frac{\partial u}{\partial t} = \nabla \cdot (g(|\nabla u|) \nabla u)
  \]
  with homogeneous Neumann boundary conditions and the initial condition \(u(0) = f(x)\), \(f\) denoting the input image.
- Constant diffusion coefficient of linear equation is replaced with a smooth non-increasing diffusivity function \(g\) satisfying
  - \(g(0) = 1\),
  - \(g(s) \geq 0\),
  - \(\lim_{s \to \infty} g(s) = 0\)
- The diffusivities become variable in both space and time.
Review - Total Variation (TV) Regularization

- Rudin et al. (1992) formulated image restoration as minimization of the total variation (TV) of a given image under certain assumptions on the noise.
- Total Variation (TV) regularization model is generally defined as:
  \[ E_{TV}(u) = \int_{\Omega} \left( \frac{1}{2} (u - f)^2 + \alpha |\nabla u| \right) dx \]
  - \( \Omega \subset \mathbb{R}^2 \) is connected, bounded, open subset representing the image domain,
  - \( f \) is an image defined on \( \Omega \),
  - \( u \) is the smooth approximation of \( f \),
  - \( \alpha > 0 \) is a scalar.

Review - TV Restoration results

- The value of \( \alpha \) specifies the relative importance of the fidelity term and thus the level of smoothing.

Review - Total Variation (TV) Regularization

- Total Variation (TV) regularization model:
  \[ E_{TV}(u) = \int_{\Omega} \left( \frac{1}{2} (u - f)^2 + \alpha |\nabla u| \right) dx \]
  - The gradient descent equation for Equation (10) is defined by:
    \[ \frac{\partial u}{\partial t} = \nabla \cdot \left( \frac{\nabla u}{|\nabla u|} \right) - \frac{1}{\alpha} (u - f); \quad \frac{\partial u}{\partial n} \bigg|_{\partial \Omega} = 0 \]
  - The value of \( \alpha \) specifies the relative importance of the fidelity term.
  - It can be interpreted as a scale parameter that determines the level of smoothing.

Review - TV Regularization and TV Flow

- TV regularization can be associated with a nonlinear diffusion filter, the so-called TV flow
- Ignoring the fidelity term in the TV regularization model leads to the PDE:
  \[ \frac{\partial u}{\partial t} = \nabla \cdot (g(|\nabla u|) \nabla u) \]
  with \( u^0 = f \) and the diffusivity function \( g(|\nabla u|) = \frac{1}{|\nabla u|} \)
- Notice that this diffusivity function has no additional contrast parameter as compared with the Perona-Malik diffusivities.
Review - Sample TV Flow results

- Corresponding smoothing process yields segmentation-like, piecewise constant images.

\[ T = 0 \quad T = 25 \quad T = 50 \quad T = 100 \quad T = 200 \quad T = 400 \]

Review - Edge Enhancing Diffusion

- Proposed by Weickert (1994)
- An anisotropic nonlinear diffusion model with better edge enhancing capabilities than the Perona-Malik model
- Can be described by the equation:
  \[ \frac{\partial u}{\partial t} = \nabla \cdot (D(\nabla u)\nabla u) \]

where
- \( u \) is the smoothed image,
- \( f \) is the input image \( u^0(x) = f(x) \),
- \( D \) represents a matrix-valued diffusion tensor that describes the smoothing directions and the corresponding diffusivities

\[ \lambda_1(|\nabla u^\sigma|) = \begin{cases} 1 & \text{if } |\nabla u^\sigma| = 0 \\ 1 - \exp\left(-\frac{3.31488}{(|\nabla u^\sigma|/\lambda)^2}\right) & \text{otherwise} \end{cases} \]

\[ \lambda_2(|\nabla u^\sigma|) = 1 \]

where \( \lambda \) denotes the contrast parameter.

- Preserves and enhances image edges by reducing the diffusivity \( \lambda \) perpendicular to edges for sufficiently large values of \( |\nabla u| \).

- Specifically, the diffusion tensor is given by the formula:

\[ D = \begin{bmatrix} (u^\sigma)_x & (u^\sigma)_y \\ (u^\sigma)_y & (u^\sigma)_x \end{bmatrix} \cdot \begin{bmatrix} \lambda_1(|\nabla u^\sigma|) & 0 \\ 0 & \lambda_2(|\nabla u^\sigma|) \end{bmatrix} \cdot \begin{bmatrix} (u^\sigma)_x & (u^\sigma)_y \\ (u^\sigma)_y & (u^\sigma)_x \end{bmatrix}^{-1} \]

Review - Sample Results of Edge Enhancing Diffusion

- Smoothing process diminishes noise and fine image details while retaining and enhancing edges as in the Perona-Malik type nonlinear diffusion.

\[ T = 0 \quad T = 50 \quad T = 100 \quad T = 200 \quad T = 400 \quad T = 800 \]

(\( \lambda = 2, \sigma = 1 \)).
### Variational Segmentation Models

- Segmentation is formalized as a functional minimization.
  - Ambrosio-Tortorelli Model (1990)
  - Shah’s Model (1996)
  - Chan-Vese Model (2001)

### Mumford-Shah (MS) Segmentation Model

\[
E_{MS}(u, \Gamma) = \beta \int_{\Omega} (u - f)^2 dx + \alpha \int_{\Omega \setminus \Gamma} |\nabla u|^2 dx + \text{length}(\Gamma)
\]

- Smoothing and edge detection processes work jointly to partition an image into segments.
- Unknown edge set $\Gamma$ of a lower dimension makes the minimization of the MS model very difficult.
- In literature several approaches for approximating the MS model are suggested.

### Mumford-Shah (MS) Segmentation Model

- Segmentation is formalized as a functional minimization:
  - Given an image $f$, compute a piecewise smooth image $u$ and an edge set $\Gamma$
  - $\Omega \subset \mathbb{R}^2$ is connected, bounded, open subset representing the image domain,
  - $f$ is an image defined on $\Omega$,
  - $\Gamma \subset \Omega$ is the edge set segmenting $\Omega$,
  - $u$ is the piecewise smooth approximation of $f$,
  - $\alpha, \beta > 0$ are the scale space parameters.

### Ambrosio-Tortorelli (AT) Approximation

\[
E_{AT}(u, v) = \int_{\Omega} \left( \beta (u - f)^2 + a (v^2 |\nabla u|^2) + \frac{1}{2} \left( \rho |\nabla v|^2 + \frac{(1 - v)^2}{\rho} \right) \right) dx
\]

- Unknown edge set $\Gamma$ is replaced with a continuous function $v(x)$
  - $v \approx 0$ along image edges
  - $v$ grows rapidly towards 1 away from edges
- The function $v$ can be interpreted as a blurred version of the edge set.
- The parameter $\rho$ specifies the level of blurring.
Ambrosio-Tortorelli (AT) Approximation: u and v processes

- Piecewise smooth image $u$ and the edge strength function $v$ are simultaneously computed via the solution of the following system of coupled PDEs:

$$
\frac{\partial u}{\partial t} = \nabla \cdot (\nu^2 \nabla u) - \frac{\beta}{\alpha} (u - f) ; \quad \frac{\partial u}{\partial n} \bigg|_{\partial \Omega} = 0
$$

$$
\frac{\partial v}{\partial t} = \nabla^2 v - 2 \frac{\alpha}{\rho} |\nabla u|^2 v - \frac{(v - 1)}{\rho^2} ; \quad \frac{\partial v}{\partial n} \bigg|_{\partial \Omega} = 0
$$

- PDE for each variable can be interpreted as a biased diffusion equation that minimizes a convex quadratic functional in which the other variable is kept fixed.

Ambrosio-Tortorelli (AT) Approximation: u process

- Keeping $v$ fixed, PDE for the process $u$ minimizes the following convex quadratic functional:

$$
\int_{\Omega} \left( \alpha v^2 |\nabla u|^2 + \beta (u - f)^2 \right) dx
$$

- Data fidelity term provides a bias that forces $u$ to be close to the original image $f$.

- In the regularization term, the edge strength function $v$ specifies the boundary points and guides the smoothing accordingly.

- Since $v \approx 0$ along the boundaries, no smoothing is carried out at the boundary points, thus the edges are preserved.
Ambrosio-Tortorelli (AT) Approximation: $v$ process

- Keeping $u$ fixed, PDE for the process $v$ minimizes the following convex quadratic functional:

$$\frac{\rho}{2} \int_{\Omega} \left(|\nabla v|^2 + \frac{1}{\rho^2} \frac{1}{1 + 2\alpha\rho|\nabla u|^2} \left(v - \frac{1}{1 + 2\alpha\rho|\nabla u|^2} \right)^2 \right) \, dx$$

- The function $v$ is nothing but a smoothing of $\frac{1}{1 + 2\alpha\rho|\nabla u|^2}$

- The smoothness term forces some spatial organization by requiring the edges to be smooth.

- Ignoring the smoothness term and letting $\rho$ go to 0, we have $v \approx \frac{1}{1 + 2\alpha|\nabla u|^2}$

Relating with the Perona-Malik Diffusion

- Replacing $v$ with $1/(1 + 2\alpha|\nabla u|^2)$, PDE for the process $u$ can be interpreted as a biased Perona-Malik type nonlinear diffusion:

$$\frac{\partial u}{\partial t} = \nabla \cdot (g(|\nabla u|)\nabla u) - \frac{\beta}{\alpha} (u - f)$$

with

$$g(|\nabla u|) = \left(\frac{1}{1 + |\nabla u|^2/\lambda^2}\right)^2$$

$$\lambda^2 = 1/(2\alpha)$$

- $\sqrt{1/(2\alpha)}$ as a contrast parameter

- Relative importance of the regularization term (scale) depends on the ratio between $\alpha$ and $\beta$.

Sample Results of the AT model

- Original model:

$$\frac{\partial u}{\partial t} = \nabla \cdot (\nabla u^2) - \frac{\beta}{\alpha} (u - f); \quad \frac{\partial u}{\partial t} \big|_{\partial \Omega} = 0$$

- Space discrete version:

$$\frac{du_{i,j}}{dt} = \frac{v_{i+\frac{1}{2},j}^2}{t+\frac{1}{2}} \cdot (u_{i+1,j} - u_{i,j}) - \frac{v_{i-\frac{1}{2},j}^2}{t-\frac{1}{2}} \cdot (u_{i,j} - u_{i-1,j})$$

$$+ \frac{v_{i,j+\frac{1}{2}}^2}{t+\frac{1}{2}} \cdot (u_{i,j+1} - u_{i,j}) - \frac{v_{i,j-\frac{1}{2}}^2}{t-\frac{1}{2}} \cdot (u_{i,j} - u_{i,j-1})$$

$$- \frac{\beta}{\alpha} (u_{i,j} - f_{i,j})$$

with $v_{i,j} = \frac{v_{i,j+1} + v_{i,j}}{2}$ and $v_{i,j} = \frac{v_{i+1,j} + v_{i,j}}{2}$

Numerical Implementation
**Numerical Implementation**

- Original model:
  \[
  \frac{\partial v}{\partial t} = \nabla^2 v - 2\alpha |\nabla u|^2 v - \frac{(v - 1)}{\rho^2}; \quad \frac{\partial v}{\partial n} \bigg|_{\partial \Omega} = 0
  \]

- Space discrete version:
  \[
  \frac{dv_{i,j}}{dt} = v_{i+1,j} + v_{i-1,j} + v_{i,j+1} + v_{i,j-1} - 4v_{i,j} - \frac{2\alpha |\nabla u_{i,j}|^2 v_{i,j}}{\rho} - \frac{(v_{i,j} - 1)}{\rho^2}.
  \]

**A Common Framework for Curve Evolution, Segmentation and Anisotropic Diffusion**

- Quadratic cost functions in the data fidelity and the smoothing terms are replaced with $L1$-functions (Shah, CVPR 1996):
  \[
  E_S(u,v) = \int_\Omega \left( \beta |u - f| + \alpha v^2 |\nabla u| + \frac{1}{2} \left( \rho |\nabla v|^2 + \frac{(1 - v)^2}{\rho} \right) \right) dx
  \]

- As $\rho \to 0$, this energy functional converges to the following functional:
  \[
  E_{S2}(u, \Gamma) = \frac{\beta}{\alpha} \int_\Omega |u - f| dx + \int_\Omega |\nabla u| dx + \int_{\Gamma} \frac{I_u}{1 + \alpha f} ds
  \]

  with $I_u = |u^+ - u^-|$ indicating the jump in $u$ across $\Gamma$, and $u^+$ and $u^-$ denote intensity values on two sides of $\Gamma$.

**Numerical Implementation**

- Space-time discrete versions:
  \[
  \frac{u_{i,j}^{k+1} - u_{i,j}^k}{\Delta t} = \left( v_{i+\frac{1}{2},j}^k \right)^2 \cdot u_{i+1,j}^k + \left( v_{i-\frac{1}{2},j}^k \right)^2 \cdot u_{i-1,j}^k
  \]
  \[
  + \left( v_{i,j+\frac{1}{2}}^k \right)^2 \cdot u_{i,j+1}^k + \left( v_{i,j-\frac{1}{2}}^k \right)^2 \cdot u_{i,j-1}^k
  \]
  \[
  - \left( \left( v_{i+\frac{1}{2},j}^k \right)^2 + \left( v_{i,j+\frac{1}{2}}^k \right)^2 \right) \cdot u_{i,j}^k
  \]
  \[
  - \frac{\beta}{\alpha} \left( u_{i,j}^{k+1} \right) \cdot f_{i,j}
  \]

  \[
  \frac{v_{i,j}^{k+1} - v_{i,j}^k}{\Delta t} = v_{i+1,j}^k + v_{i-1,j}^k + v_{i,j+1}^k + v_{i,j-1}^k - 4v_{i,j}^k
  \]
  \[
  - \frac{\alpha \left( u_{i+1,j}^k - u_{i-1,j}^k \right)^2 + \left( u_{i,j+1}^k - u_{i,j-1}^k \right)^2}{2\rho} - \frac{(v_{i,j}^{k+1} - 1)}{\rho^2}
  \]

**A Common Framework for Curve Evolution, Segmentation and Anisotropic Diffusion**

- Minimizing the energy functional results in the following system of coupled PDEs:
  \[
  \frac{\partial u}{\partial t} = 2\nabla v \cdot \nabla u + v |\nabla u| \text{curv}(u) - \frac{\beta}{\alpha \rho} |\nabla u| \frac{(u - f)}{|u - f|}; \quad \frac{\partial u}{\partial n} \bigg|_{\partial \Omega} = 0
  \]

  \[
  \frac{\partial v}{\partial t} = \nabla^2 v - \frac{2\alpha |\nabla u|^2 v}{\rho^2} - \frac{(v - 1)}{\rho^2}; \quad \frac{\partial v}{\partial n} \bigg|_{\partial \Omega} = 0
  \]

  with \( \text{curv}(u) = \nabla \cdot \left( \frac{\nabla u}{|\nabla u|} \right) \)

- Replacing $L2$-norms in both the data fidelity and the smoothness terms by their $L1$-norms generates shocks in $u$ and thus object boundaries are recovered as actual discontinuities.
Sample Results of Shah (CVPR96)

• Smoothing process of $u$ gives rise to more cartoon-like, piecewise constant images but with some unintuitive regions.

Context-Guided Image Smoothing

• Contextual knowledge extracted from local image regions guides the regularization process.

Challenging Cases

Context-Guided Image Smoothing

• Contextual knowledge extracted from local image regions guides the regularization process.
Context-Guided Image Smoothing

- Contextual knowledge extracted from local image regions guides the regularization process.

The Roles of $\phi$ and $V$

1. Eliminating an accidentally occurring event
   - e.g., a high gradient due to noise
   - $V=1$, $\phi$ is low for accidental occurrences
     \[(cv)_i^2 = (\phi_i v_i + (1 - \phi_i) 1)^2\]

2. Preventing an accidental elimination of a feature of interest
   - e.g., encourage edge formation
   - $V=0$, $\phi$ is low for meaningful occurrences
     \[(cv)_i^2 = (\phi_i v_i + (1 - \phi_i) 0)^2\]

\[
\frac{\partial v}{\partial t} = \nabla^2 v - \frac{2\alpha |\nabla u|^2 v}{\rho} - \frac{(v - 1)}{\rho^2}; \quad \frac{\partial v}{\partial n}|_{\partial\Omega} = 0
\]

\[
\frac{\partial u}{\partial t} = \nabla \cdot (cv)^2 \nabla u) - \frac{\beta}{\alpha} (u - f); \quad \frac{\partial u}{\partial n}|_{\partial\Omega} = 0
\]

\[cv = \phi v + (1 - \phi) V \quad \phi \in [0, 1] \quad V \in [0, 1]\]
Experimental Results

• Suggested contextual measures:
  1. Directional consistency of edges
      - shapes have smooth boundaries
  2. Edge Continuity
      - gap filling
  3. Texture Edges
      - boundary between different textured regions
  4. Local Scale
      - Resolution varies throughout the image

Directional Consistency

Coalition of Directional Consistency, Edge Continuity and Texture Edges

Active Contours Without Edges

- Level sets provide an implicit contour representation where an evolving curve is represented with the zero-level line of a level set function.

Image credit: Chan & Vese, 2001
Active Contours Without Edges

• Basic idea: Fitting term

\[ \int_{\text{inside}(C)} |u_0 - c_1|^2 dx dy + \int_{\text{outside}(C)} |u_0 - c_2|^2 dx dy \]

where \( c_1 = \text{average of } u_0 \text{ inside } C \)
\( c_2 = \text{average of } u_0 \text{ outside } C \)

Fit > 0  Fit > 0  Fit > 0  Fit ≈ 0

• Minimize: the Fitting term + Length(C)

Slide credit: L. Vese

Active Contours Without Edges

• A level-set based approximation of the Mumford-Shah model proposed by Chan and Vese (2001):

\[
E_{CV}(c_1, c_2, \phi) = \lambda_1 \int_{\Omega} (f - c_1)^2 H(\phi) dx + \lambda_2 \int_{\Omega} (f - c_2)^2 (1 - H(\phi)) dx \\
+ \mu \int_{\Omega} |\nabla H(\phi)| dx
\]

where \( \lambda_1, \lambda_2 > 0 \) and \( \mu > 0 \) are fixed parameters.

• Length parameter \( \mu \) can be interpreted as a scale parameter. It determines the relative importance of the length term.

• Possibility of detecting smaller objects/regions increases with decreasing \( \mu \).

Active Contours Without Edges

• Model represents the segmented image with the variables \( c_1, c_2 \) and \( H(\phi) \), where \( H(\phi) \) denotes the heaviside function of the level set function \( \phi \):

\[
H(z) = \begin{cases} 
1 & \text{if } z \geq 0 \\
0 & \text{if } z < 0 
\end{cases}
\]
Active Contours Without Edges

\[
E_{CV}(c_1, c_2, \phi) = \lambda_1 \int_{\Omega} (f - c_1)^2 H(\phi) dx + \lambda_2 \int_{\Omega} (f - c_2)^2 (1 - H(\phi)) dx \\
+ \mu \int_{\Omega} |\nabla H(\phi)| dx
\]

where \(\lambda_1, \lambda_2 > 0\) and \(\mu \geq 0\) are fixed parameters.

Active Contours Without Edges

- Segmentation involves minimizing the energy functional with respect to \(c_1, c_2,\) and \(\phi\).
- Keeping \(c_1\) and \(c_2\) fixed and using the calculus of variations for the given functional, the gradient descent equation for the evolution of \(\phi\) is derived as:

\[
\frac{\partial \phi}{\partial t} = \delta(\phi) \left[ \mu \nabla \cdot \left( \frac{\nabla \phi}{|\nabla \phi|} \right) - \lambda_1 (f - c_1)^2 + \lambda_2 (f - c_2)^2 \right]
\]

Sample result of the Chan-Vese Model

- As the zero-level line of the evolving level set function \(\phi\) is attracted to object boundaries, a more accurate piecewise constant approximations of the original image \(f\) is recovered.
Sample result of the Chan-Vese Model

- As the zero-level line of the evolving level set function $\phi$ is attracted to object boundaries, a more accurate piecewise constant approximations of the original image $f$ is recovered.

Numerical Implementation

- In the numerical approximation, regularized form of the Heaviside function is used:

\[
H_\varepsilon(z) = \frac{1}{2} \left( 1 + \frac{2}{\pi} \arctan \left( \frac{z}{\varepsilon} \right) \right)
\]

\[
\delta_\varepsilon(z) = \frac{dH_\varepsilon(z)}{dz} = \frac{1}{\pi \varepsilon^2 + z^2}
\]

Sample result of the Chan-Vese Model

- As the zero-level line of the evolving level set function $\phi$ is attracted to object boundaries, a more accurate piecewise constant approximations of the original image $f$ is recovered.

Numerical Implementation

- Space-time discrete version:

\[
\frac{\phi_{i,j}^{k+1} - \phi_{i,j}^{k}}{\Delta t} = \delta(\phi_{i,j}^k) \left[ \mu \Delta_x^+ \cdot \frac{\Delta_x^- \phi_{i,j}^{k+1}}{\sqrt{(\Delta_x^+ \phi_{i,j}^k)^2 + (\phi_{i,j+1}^k - \phi_{i,j-1}^k)^2 / 4}} ight] + \mu \Delta_y^- \cdot \frac{\Delta_y^+ \phi_{i,j}^{k+1}}{\sqrt{(\phi_{i+1,j}^k - \phi_{i-1,j}^k)^2 / 4 + (\Delta_y^+ \phi_{i,j}^k)^2}}
\]

\[
- \lambda_1 \left( f_{i,j} - c_1(\phi^k) \right)^2 + \lambda_2 \left( f_{i,j} - c_2(\phi^k) \right)^2
\]

with

\[
\Delta_x^+ \phi_{i,j} = \phi_{i,j} - \phi_{i-1,j}, \quad \Delta_x^- \phi_{i,j} = \phi_{i+1,j} - \phi_{i,j},
\]

\[
\Delta_y^+ \phi_{i,j} = \phi_{i,j} - \phi_{i,j-1}, \quad \Delta_y^- \phi_{i,j} = \phi_{i,j+1} - \phi_{i,j}.
\]
