Graphical Models

Erkut Erdem Hacettepe University Computer Vision Lab (HUCVL)

Energy Minimization

• Many vision tasks are naturally posed as energy minimization problems on a rectangular grid of pixels:

 $E(u) = E_{data}(u) + E_{smoothness}(u)$

- The data term E_{data}(u) expresses our goal that the optimal model u be consistent with the measurements.
- The smoothness energy $E_{smoothness}(u)$ is derived from our prior knowledge about plausible solutions.
- Recall Mumford-Shah functional

Sample Vision Tasks

- <u>Image Denoising</u>: Given a noisy image *I(x,y)*, where some measurements may be missing, recover the original image *I(x, y)*, which is typically assumed to be smooth.
- <u>Image Segmentation:</u> Assign labels to pixels in an image, e.g., to segment foreground from background.
- Stereo matching
- Surface Reconstruction
- ...

Smoothing out cluster assignments

• Assigning a cluster label per pixel may yield outliers:

• How to ensure they are spatially smooth?

Solution

P(foreground | image)

Normalizing constant $P(\mathbf{y};\theta,data) = \frac{1}{Z} \prod_{i=1..N} f_1(y_i;\theta,data) \prod_{i,j \in edges} f_2(y_i,y_j;\theta,data)$ Labels to be Individual Pairwise predicted predictions predictions

Encode dependencies between pixels

Writing Likelihood as an "Energy"

Markov Random Fields

Markov Random Fields

D. Hoiem

• Example: "label smoothing" grid

 $Energy(\mathbf{y};\theta,data) = \sum_{i} \psi_{1}(y_{i};\theta,data) + \sum_{i,j \in edges} \psi_{2}(y_{i},y_{j};\theta,data)$

Binary MRF Example

- Consider the following energy function for two binary random variables, $y_1 \& y_2$.

 $E(y_1, y_2) = \psi_1(y_1) + \psi_2(y_2) + \psi_{12}(y_1, y_2)$

Binary MRF Example

Consider the following energy function for two binary random variables, y₁ & y₂.
0 1

Binary MRF Example

Consider the following energy function for two binary random variables, y₁ & y₂.

$$E(y_1, y_2) = \psi_1(y_1) + \psi_2(y_2) + \psi_{12}(y_1, y_2)$$

= $5\bar{y}_1 + 2y_1$
 ψ_1
+ $\bar{y}_2 + 3y_2$
 ψ_2
+ $3\bar{y}_1y_2 + 4y_1\bar{y}_2$
 ψ_{12}

where $\overline{y}_1 = 1 - y_1$ and $\overline{y}_2 = 1 - y_2$.

Probability Table			
<i>y</i> ₁	<i>y</i> ₂	E	Р
0	0	6	0.244
0	1	11	0.002
1	0	7	0.090
1	1	5	0.664

Image Denoising

- Given a noisy image v, perhaps with missing pixels, recover an image u that is both smooth and close to v.
- Classical techniques:
 - Linear filtering (e.g. Gaussian filtering)
 - Median filtering
 - Wiener filtering

Denoising as a Probabilistic Inference

• Perform maximum a posteriori (MAP) estimation by maximizing the a posteriori distribution:

p(true image | noisy image) = p(u | v)

- By Bayes theorem: $p(u|v) = \frac{p(v|u)p(u)}{p(v)}$ normalization term
- If we take logarithm:

$$\log p(u \mid v) = \log p(v \mid u) + \log p(u) - \log p(v)$$

likelihood of noisy image

given true image

• MAP estimation corresponds to minimizing the encoding cost

 $E(u) = -\log p(v \mid u) - \log p(u)$

Modeling the Likelihood

• We assume that the noise at one pixel is independent of the others.

$$p(v \mid u) = \prod_{i,j} p(v_{ij} \mid u_{ij})$$

• We assume that the noise at each pixel is additive and Gaussian distributed:

$$p(v_{ij} \mid u_{ij}) = G_{\sigma}(v_{ij} - u_{ij})$$

• Thus, we can write the likelihood:

$$p(v \mid u) = \prod_{i,j} G_{\sigma}(v_{ij} - u_{ij})$$

Modeling the Prior Modeling the Prior Model the prior distribution of true images?

- What does that even mean?
- Howedown model the prior distribution of true images?
- What a diouter thus the among the set of all possible images.
 - We want the prior to describe how probable it is (a-priori) to have a particular true image among the set of all possible images.

Natural Images

 What distinguishes "natural" images from "fake" ones?

Simple Observation

Simple ObservationNearby pixels often have a similar intensity/color:

• But sometimes there are large intensity/color changes.

MRF-based Image Denoising

- Let each pixel be a hode in a graph $\mathcal{G}^{r} = (\mathcal{V}, \mathcal{E})$ with 4-connected neighborhoods.

• The energy function is given by

$$E(u) = \sum_{i \in \mathcal{V}} D(u_i) + \sum_{(i,j) \in \mathcal{E}} V(u_i, u_j)$$

- Unary (clique) potentials D stem from the measurement model, penalizing the discrepancy between the data v and the solution u

- Interaction (clique) potentials V provide a definition of smoothness, penalizing changes $\mathrm{in}u$. between pixels and their neighbors.

Denoising as Inference

- Goal: Find the image u that minimizes E(u)
- Several options for MAP estimation process:
 - Gradient techniques
 - Gibbs sampling
 - Simulated annealing
 - Belief propagation
 - Graph cut

— ...

Quadratic Potentials in 1D

• Let v be the sum of a smooth 1D signal u and IID Gaussian noise e: where $u = (u_1, ..., u_N)$, $v = (v_1, ..., v_N)$, and $e = (e_1, ..., e_N)$.

• With Gaussian IID noise, the negative log likelihood provides a quadratic *data term*. If we let the *smoothness term* be quadratic as well, then up to a constant, the log posterior is

$$E(u) = \sum_{n=1}^{N} (u_n - v_n)^2 + \lambda \sum_{n=1}^{N-1} (u_{n+1} - u_n)^2$$

Quadratic Potentials in 1D

• To find the optimal u^* , we take derivatives of E(u) with respect to u_n :

$$\frac{\partial E(u)}{\partial u_n} = 2\left(u_n - v_n\right) + 2\lambda\left(-u_{n-1} + 2u_n - u_{n+1}\right)$$

and therefore the necessary condition for the critical point is

$$u_n + \lambda \left(-u_{n-1} + 2u_n - u_{n+1} \right) = v_n$$

• For endpoints we obtain different equations:

$$u_1 + \lambda (u_1 - u_2) = v_1$$
 N linear equations
 $u_N + \lambda (u_N - u_{N-1}) = v_N$ in the N unknowns

J. Fleet

Missing Measurements

• Suppose our measurements exist at a subset of positions, denoted P. Then we can write the energy function as

$$E(u) = \sum_{n \in P} (u_n - v_n)^2 + \lambda \sum_{\text{all } n} (u_{n+1} - u_n)^2$$

• At locations n where no measurement exists, we have:

$$-u_{n-1} + 2u_n - u_{n+1} = 0$$

• The Jacobi update equation in this case becomes:

$$u_n^{(t+1)} = \begin{cases} \frac{1}{1+2\lambda} \left(v_n + \lambda u_{n-1}^{(t)} + \lambda u_{n+1}^{(t)} \right) & \text{for } n \in P, \\ \frac{1}{2} \left(u_{n-1}^{(t)} + u_{n+1}^{(t)} \right) & \text{otherwise} \end{cases}$$

2D Image Smoothing

• For 2D images, the analogous energy we want to minimize becomes:

$$\begin{split} E(u) &= \sum_{n,m \in P} (u[n,m] - v[n,m])^2 \\ &+ \lambda \sum_{\text{all } n,m} (u[n+1,m] - u[n,m])^2 + (u[n,m+1] - u[n,m])^2 \end{split}$$

where P is a subset of pixels where the measurements v are available.

Looks familiar??

Robust Potentials

- Quadratic potentials are not robust to *outliers* and hence they over-smooth edges. These effects will propagate throughout the graph.
- Instead of quadratic potentials, we could use a robust error function ρ :

$$E(u) = \sum_{n=1}^{N} \rho(u_n - v_n, \sigma_d) + \lambda \sum_{n=1}^{N-1} \rho(u_{n+1} - u_n, \sigma_s),$$

where σ_d and σ_s are scale parameters.

Robust Potentials

• <u>Example:</u> the *Lorentzian* error function

$$\rho(z,\sigma) = \log\left(1 + \frac{1}{2}\left(\frac{z}{\sigma}\right)^2\right), \quad \rho'(z,\sigma) = \frac{2z}{2\sigma^2 + z^2}.$$

Influence function

Robust Potentials

- <u>Example:</u> the *Lorentzian* error function
- Smoothing a noisy step edge

Robust Image Smoothing

• A Lorentzian smoothness potential encourages an approximately piecewise constant result:

Original image

Output of robust smoothing

Edges

Image Segmentation

- Given an image, partition it into meaningful regions or segments.
- Approaches
 - Variational segmentation models
 - Clustering-based approaches (K-means, Mean Shift)
 - Graph-theoretic formulations
- MRF-based techniques

MRFs and Graph-cut

Markov Random Fields

• Example: "label smoothing" grid

 $Energy(\mathbf{y};\theta,data) = \sum_{i} \psi_{1}(y_{i};\theta,data) + \sum_{i,j \in edges} \psi_{2}(y_{i},y_{j};\theta,data)$

Solving MRFs with graph cuts

<u>Main idea:</u>

- Construct a graph such that every *st*-cut corresponds to a joint assignment to the variables y
- The cost of the cut should be equal to the energy of the assignment, E(y; data)*.
- The minimum-cut then corresponds to the minimum energy assignment, y* = argmin_y E(y; data).

 $Energy(\mathbf{y};\theta,data) = \sum_{i} \psi_{1}(y_{i};\theta,data) + \sum_{i,j \in edges} \psi_{2}(y_{i},y_{j};\theta,data)$

$$Energy(\mathbf{y};\theta,data) = \sum_{i} \psi_{1}(y_{i};\theta,data) + \sum_{i,j \in edges} \psi_{2}(y_{i},y_{j};\theta,data)$$

The st-Mincut Problem

Graph (V, E, C)
Vertices V =
$$\{v_1, v_2 ... v_n\}$$

Edges E = $\{(v_1, v_2)\}$
Costs C = $\{c_{(1, 2)}\}$

The st-Mincut Problem

What is a st-cut?

The st-Mincut Problem

What is a st-cut?

An st-cut (S,T) divides the nodes between source and sink.

What is the cost of a st-cut?

Sum of cost of all edges going from S to T
The st-Mincut Problem

What is a st-cut?

An st-cut (S,T) divides the nodes between source and sink.

What is the cost of a st-cut?

Sum of cost of all edges going from S to T

What is the st-mincut?

st-cut with the minimum cost

So how does this work?

Construct a graph such that:

- 1. Any st-cut corresponds to an assignment of x
- 2. The cost of the cut is equal to the energy of x : E(x)

[Hammer, 1965] [Kolmogorov and Zabih, 2002]

st-mincut and Energy Minimization

$$E(x) = \sum_{i} \Theta_{i}(x_{i}) + \sum_{i,j} \Theta_{ij}(x_{i},x_{j})$$

For all ij $\Theta_{ij}(0,1) + \Theta_{ij}(1,0) \ge \Theta_{ij}(0,0) + \Theta_{ij}(1,1)$
$$f = Equivalent (transformable)$$
$$E(x) = \sum_{i} c_{i}x_{i} + \sum_{i,j} c_{ij}x_{i}(1-x_{j})$$

 $E(a_1, a_2)$

 $E(a_1,a_2) = 2a_1 + 5\bar{a}_1$

 $E(a_1, a_2) = 2a_1 + 5\bar{a}_1 + 9a_2 + 4\bar{a}_2$

$$\mathsf{E}(\mathsf{a}_1,\mathsf{a}_2) = 2\mathsf{a}_1 + 5\bar{\mathsf{a}}_1 + 9\mathsf{a}_2 + 4\bar{\mathsf{a}}_2 + 2\mathsf{a}_1\bar{\mathsf{a}}_2$$

 $\mathsf{E}(\mathsf{a}_1,\mathsf{a}_2) = 2\mathsf{a}_1 + 5\bar{\mathsf{a}}_1 + 9\mathsf{a}_2 + 4\bar{\mathsf{a}}_2 + 2\mathsf{a}_1\bar{\mathsf{a}}_2 + \bar{\mathsf{a}}_1\mathsf{a}_2$

 $\mathsf{E}(\mathsf{a}_1,\mathsf{a}_2) = 2\mathsf{a}_1 + 5\bar{\mathsf{a}}_1 + 9\mathsf{a}_2 + 4\bar{\mathsf{a}}_2 + 2\mathsf{a}_1\bar{\mathsf{a}}_2 + \bar{\mathsf{a}}_1\mathsf{a}_2$

 $E(a_1, a_2) = 2a_1 + 5\bar{a}_1 + 9a_2 + 4\bar{a}_2 + 2a_1\bar{a}_2 + \bar{a}_1a_2$

 $E(a_1, a_2) = 2a_1 + 5\bar{a}_1 + 9a_2 + 4\bar{a}_2 + 2a_1\bar{a}_2 + \bar{a}_1a_2$

How to compute the st-mincut?

Solve the dual maximum flow problem

Compute the maximum flow between Source and Sink s.t.

Edges: Flow < Capacity

Nodes: Flow in = Flow out

Min-cut\Max-flow Theorem

In every network, the maximum flow equals the cost of the st-mincut

Assuming non-negative capacity

Flow = 0
