

CMP 784 – Practical 2: Convolutional Neural Networks

Due date: Thursday, 21-11-2024, 11:59 PM.

Overview

The goal of this assignment is to get you familiarize with convolutional neural networks (CNNs)¹.

First, we will train a convolutional neural network for a task known as image colourization. Given a grayscale image, we will predict the colour at each pixel. This a difficult problem for many reasons, one of which being that it is ill-posed: for a single grayscale image, there can be multiple, equally valid colourings. In the second half of the assignment, we will perform fine-tuning on a pre-trained semantic segmentation model. Semantic segmentation attempts to clusters the areas of an image which belongs to the same object (label), and treats each pixel as a classification problem. We will fine-tune a pre-trained conv net featuring dilated convolution to segment flowers from the Oxford17 flower dataset².

Setting Up

We recommend that you use Colab (<https://colab.research.google.com/>) for the assignment, as all the assignment notebooks have been tested on Colab. Otherwise, if you are working on your own environment, you will need to install Python, PyTorch (<https://pytorch.org>), iPython Notebooks, SciPy, NumPy and scikit-learn. Check out the websites of the course and relevant packages for more details.

Download the Python notebook file `cnn.ipynb`, which contains the starter code for the assignment, from the course webpage. Even though you only have to modify a few specific locations in the code, you may want to read through this code before starting the assignment. To setup the Colab environment, you will need to upload this notebook file using the upload tab at <https://colab.research.google.com/>.

Part A: Colourization as Classification

In this section, we will perform image colourization using a convolutional neural network. Given a grayscale image, we wish to predict the color of each pixel. We have provided a subset of 24 output colours, selected using k-means clustering³. The colourization task will be framed as a pixel-wise classification problem, where we will label each pixel with one of the 24 colours. For simplicity, we measure distance in RGB space. This is not ideal but reduces the software dependencies for this assignment.

We will use the CIFAR-10 data set, which consists of images of size 32×32 pixels. For most of the questions we will use a subset of the dataset. The data loading script is included with the notebook, and should download automatically the first time it is loaded. If you have trouble downloading the file, you can also do so manually from:

<http://www.cs.toronto.edu/~kriz/cifar-10-python.tar.gz>.

Helper code for Part A is provided in `cnn.ipynb`, which will define the main training loop as well as utilities for data manipulation. Run the helper code to setup for this question and answer the following questions.

¹Adapted from the practical developed by Lisa Zhang for deep learning class

²<http://www.robots.ox.ac.uk/~vgg/data/flowers/17/>

³https://en.wikipedia.org/wiki/K-means_clustering

1. Complete the model `CNN`, following the diagram provided below. Use the PyTorch layers `nn.ReLU`, `nn.BatchNorm2d`, `nn.Upsample`, and `nn.MaxPool2d`, but do not use `nn.Conv2d`. Instead, use the convolutional layer `MyConv2d` included in the file to better understand its internals. Your CNN should be configurable by parameters `kernel`, `num_filters`, `num_colours`, and `num_in_channels`. In the diagram, `num_filters` and `num_colours` are denoted `NF` and `NC`, respectively. Use the following parameterizations (if not specified, assume default parameters):

- `MyConv2d`: Number of output filters to use shown after the hyphen. For example, `MyConv2D-2NF` has `2NF` output filters. Set kernel size to parameter `kernel`. Set number of input filters for first `MyConv2d` to `num_in_channels`.
- `nn.BatchNorm2d`: the number of features to use for a layer is shown after the hyphen.
- `nn.Upsample`: use `scaling_factor = 2`
- `nn.MaxPool2d`: use `kernel_size = 2`

Grouping layers according to the diagram (those not separated by white space) by using `nn.Sequential` containers will aid implementation of the `forward` method.

2. Run main training loop of `CNN`. This will train the CNN for a few epochs using the crossentropy objective. It will generate some images showing the trained result at the end. Do these results look good to you? Why or why not?
3. Compute the number of weights, outputs, and connections in the model, as a function of `NF` and `NC`. Compute these values when each input dimension (width/height) is doubled. Report all 6 values.
4. Consider an pre-processing step where each input pixel is multiplied elementwise by scalar a , and is shifted by some scalar b . That is, where the original pixel value is denoted x , the new value is calculated $y = ax + b$. Assume this operation does not result in any overflows. How does this pre-processing step affect the output of the conv net from Question 1 and 2?

Part B: Skip Connections

A skip connection in a neural network is a connection which skips one or more layer and connects to a later layer. We will introduce skip connections to our previous model.

1. Add a skip connection from the first layer to the last, second layer to the second last, etc. That is, the final convolution should have both the output of the previous layer and the initial grayscale input as input. This type of skip-connection is introduced by Ronneberger et al. (MICCAI 2015), and is called a “UNet”. Following the CNN class that you have completed, complete the `__init__` and `forward` methods of the `UNet` class in Part B of the notebook. Hint: You will need to use the function `torch.cat`.
2. Train the model for at least 25 epochs and plot the training curve using a batch size of 100.
3. How does the result compare to the previous model? Did skip connections improve the validation loss and accuracy? Did the skip connections improve the output qualitatively? How? Give at least two reasons why skip connections might improve the performance of our CNN models.
4. Re-train a few more “UNet” models using different mini batch sizes with a fixed number of epochs. Describe the effect of batch sizes on the training/validation loss, and the final image output.

Part C: Fine-tune Semantic Segmentation Model

In the previous two parts, we worked on training models for image colourization. Now we will switch gears and perform semantic segmentation by fine-tuning a pre-trained model.

Semantic segmentation can be considered as a pixel-wise classification problem where we need to predict the class label for each pixel. Fine-tuning is often used when you only have limited labeled data.

Here, we take a pre-trained model on the Microsoft COCO [Lin et al., 2014] dataset and finetune it to perform segmentation with the classes it was never trained on. To be more specific, we use *deeplabv3* [Chen et al., 2017]⁴ pre-trained model and fine-tune it on the Oxford17 [Nilsback and Zisserman, 2008] flower dataset.

We simplify the task to be a binary semantic segmentation task (background and flower). In the following code, you will first see some examples from the Oxford17 dataset and load the finetune the model by truncating the last layer of the network and replacing it with a randomly initialized convolutional layer. Note that we only update the weights of the newly introduced layer.

1. For this assignment, we want to fine-tune only the last layer in our downloaded *deeplabv3*. We do this by keeping track of weights we want to update in `learned_parameters`. Use the PyTorch utility `Model.named_parameters()`⁵, which returns an iterator over all the weight matrices of the model. The last layer weights have names prefix “`classifier.4`”. We will select the corresponding weights then passing them to `learned_parameters`.

Complete the `train` function in Part C of the notebook by adding 2-3 lines of code where indicated.

2. For fine-tuning we also want to
 - use `Model.requires_grad_()` to prevent back-prop through all the layers that should be frozen.
 - replace the last layer with a new `nn.Conv2d` layer with appropriate input output channels and kernel sizes. Since we are performing binary segmentation for this assignment, this

⁴deeplabv3 details: https://pytorch.org/hub/pytorch_vision_deeplabv3_resnet101/

⁵See examples at <https://pytorch.org/docs/stable/nm.html>

new layer should have 2 output channels.

Complete the script in Question 2 of Part C by adding around 2 lines of code and train the model.

3. Visualize the predictions by running the helper code provided.
4. Consider a case of fine-tuning a pre-trained model with n number of layers. Each of the layers have a similar number of parameters, so the total number of parameters for the model is proportional to n . Describe the difference in memory complexity in terms of n between fine-tuning an entire pre-trained model versus fine-tuning only the last layer (freezing all the other layers). What about the computational complexity?
5. If we increase the height and the width of the input image by a factor of 2, how does this affect the memory complexity of fine-tuning? What about the number of parameters?

Grading

The assignment will be graded out of 4: 0 (*no submission*), 1 (*an attempt at a solution*), 2 (*a partially correct solution*), 3 (*a mostly correct solution*), 4 (*a correct solution*), 5 (*a particularly creative or insightful solution*).

What to Hand In

You are required to submit all your code along with a report in pdf format. The codes you will submit should be well commented and in the form of a Jupyter notebook. Your report should include the answers to the given questions and your observations about your experimental analysis. Finally, prepare a ZIP file named `name-surname(s)-practical2.zip` containing

- Your code file `cnn.ipynb`
- A pdf file titled `practical2-report.pdf` containing the following:
 - Answers to the questions from Part A
 - Answer to the question from Part B
 - Answer to the question from Part C

The ZIP file will be submitted via email to `erkut@cs.hacettepe.edu.tr`.

Late policy

You may use up to five *extension* days (in total) over the course of the semester for the programming assignments. Late submission will not be allowed.

Academic Integrity

All work on assignments must be done individually unless stated otherwise. You are encouraged to discuss with your other classmates about the given assignments, but these discussions should be carried out in an abstract way. That is, discussions related to a particular solution to a specific problem (either in actual code or in the pseudocode) will not be tolerated. In short, turning in someone else's work, in whole or in part, as your own will be considered as a violation of academic integrity. Please note that the former condition also holds for the material found on the web as everything on the web has been written by someone else.
