Pushdown Automata
Pushdown Automata

- Pushdown automata accept exactly context free languages.

- A pushdown automata (PDA) is essentially an NFA with a stack.

- On a transition, a PDA:
  1. Consumes an input symbol.
  2. Goes to a new state (or stays in the old).
  3. Replaces the top of the stack by any string (does nothing, pops the stack, or pushes a string onto the stack)

![Diagram of a Pushdown Automaton]
A pushdown Automata (PDA) is a seven-tuple:

\[ P = (Q, \Sigma, \Gamma, \delta, q_0, Z_0, F), \]

where

- \( Q \) is a finite set of states,
- \( \Sigma \) is a finite input alphabet,
- \( \Gamma \) is finite stack alphabet,
- \( \delta: Q \times \Sigma \cup \{\varepsilon\} \times \Gamma \rightarrow 2^{Q \times \Gamma^*} \) is the transition function,
- \( q_0 \) is a start state,
- \( Z_0 \) is the start symbol for the stack, and
- \( F \) is the set of accepting states.
Consider a CFL \( L_{ww^r} = \{ \text{ww}^r : w \in \{0,1\}^* \} \)

A pushdown automaton \( P \) for the language \( L_{ww^r} \) is as follows:

\[
P = ( \{ q_0, q_1, q_2 \}, \{0,1\}, \{0,1,Z_0\}, \delta, q_0, Z_0, \{q_2\} )
\]
Pushdown Automata – Example

Table Representation of Transition Function

- Consider a CFL \( L_{ww^r} = \{ ww^r : w \in \{0,1\}^* \} \)
- A pushdown automaton \( P \) for the language \( L_{ww^r} = \{ ww^r : w \in \{0,1\}^* \} \) is actually a seven tuple:

\[
P = ( \{ q_0, q_1, q_2 \}, \{0,1\}, \{0,1,Z_0\}, \delta, q_0, Z_0, \{q_2\} )
\]

where its transition function can be also shown by a table.
### Pushdown Automata – Example

BBM401 Automata Theory and Formal Languages
Instantaneous Descriptions (ID) of a PDA

• A PDA goes from configuration to configuration when consuming input.

• The configuration of a PDA is represented by a triple \((q,w,\gamma)\) where
  1. \(q\) is a the state,
  2. \(w\) is the remaining input, and
  3. \(\gamma\) is the stack contents

• A configuration triple is called an instantaneous description, or ID, of the pushdown automaton.
We need a notation that describes changes in the state, the input, and stack.

Let $P = (Q, \Sigma, \Gamma, \delta, q_0, Z_0, F)$ be a PDA. We define a move $\vdash$ as follows.

- If $(p, \alpha) \in \delta(q, a, X)$ contains $(p, \alpha)$ where $q \in Q$, $a \in \Sigma \cup \{\varepsilon\}$, $X \in \Gamma$ and $\alpha \in \Gamma^*$. Then for all strings $w \in \Sigma^*$ and $\beta \in \Gamma^*$, we have a move (transition):
  $$(q, aw, X\beta) \vdash (p, w, \alpha\beta)$$

This move reflects the idea that, by consuming $a$ (which may be $\varepsilon$) from the input and replacing $X$ on top of the stack by $\alpha$ we can go from state $q$ to state $p$.

  - Note that what remains on the input, $w$, and what is below the top of the stack, $\beta$, do not influence the action of the PDA, they are merely carried along.
PDA Moves - turnstile $\vdash^*$ Notation

Computation

• To represent a sequence of zero or more moves of the PDA, we use $\vdash^*$.

• A sequence of moves is also called as computation.

BASIS:

$I \vdash^* I$ for any ID $I$.

INDUCTION:

If $I \vdash^* J$ if there exists ID $K$ such that $I \vdash K$ and $K \vdash^* J$. 
On input 1111 the PDA has the following computation sequences:

Arrows represent move ⊢ relation.
A sequence of moves (a computation):

\((q_0, 1111, Z_0) \vdash (q_0, 111, 1Z_0) \vdash (q_0, 11, 11Z_0) \vdash (q_1, 1, 1Z_0) \vdash (q_1, \varepsilon, Z_0) \vdash (q_2, \varepsilon, Z_0)\)

Thus, \((q_0, 1111, Z_0) \vdash^* (q_2, \varepsilon, Z_0)\)
Actions of Example PDA

- Initial configuration (initial ID): \((q_0, 1111, Z_0)\)
Actions of Example PDA

\[(q_0, 1111, Z_0) \vdash (q_0, 111, 1Z_0)\]

\[
\begin{array}{c}
1 1 1 1 \\
\uparrow \\

1, 1 / 11 \\
\end{array}
\quad
\begin{array}{c}
0, 0 / \epsilon \\
\epsilon, 0 / 0 \\
\epsilon, 1 / 1 \\
\end{array}
\]
Actions of Example PDA

(q₀,1111,Z₀) ⊢ (q₀,111,1Z₀) ⊢ (q₀,11,11Z₀)
Actions of Example PDA

\[(q_0,1111,Z_0) \vdash (q_0,111,1Z_0) \vdash (q_0,11,11Z_0)\]

\[\vdash (q_1,11,11Z_0)\]
Actions of Example PDA

\[(q_0, 1111, Z_0) \vdash (q_0, 111, 1Z_0) \vdash (q_0, 11, 11Z_0)\]

\[\vdash (q_1, 11, 11Z_0) \vdash (q_1, 1, 1Z_0)\]
Actions of Example PDA

\[(q_0, 1111, Z_0) \vdash (q_0, 111, 1Z_0) \vdash (q_0, 11, 11Z_0)\]

\[\vdash (q_1, 11, 11Z_0) \vdash (q_1, 1, 1Z_0) \vdash (q_1, \varepsilon, Z_0)\]
Actions of Example PDA

\[(q_0,1111,Z_0) \vdash (q_0,111,1Z_0) \vdash (q_0,11,11Z_0)\]
\[\vdash (q_1,11,11Z_0) \vdash (q_1,1,1Z_0) \vdash (q_1,\varepsilon,Z_0) \vdash (q_2,\varepsilon,Z_0)\]
On input 01 the PDA has the following computation sequences:

- $(q_0,01,Z_0)$
- $(q_0,1,Z_0)$
- $(q_1,01,Z_0)$
- $(q_2,01,Z_0)$
- $(q_0,\epsilon,10Z_0)$
- $(q_1,\epsilon,10Z_0)$
- $(q_2,\epsilon,10Z_0)$
- $(q_1,1,0Z_0)$
- $(q_2,1,0Z_0)$

All computations end with an ID whose state is NOT a final state or the input string is NOT consumed. Thus, 01 is NOT accepted by this PDA.

- $(q_1,\epsilon,10Z_0)$ $q_1$ is NOT a final state, and $q_1$ does not have any move.
- $(q_2,01,Z_0)$ the input (01) is NOT consumed, and $q_2$ does not have any move.
- $(q_2,1,0Z_0)$ the input (1) is NOT consumed, and $q_2$ does not have any move.
Languages of PDA
The Languages of a PDA

• In our example, we have assumed that a PDA accepts its input by consuming it and entering an accepting state.

• This approach is called as "Acceptance By Final State".

• There is a second approach known as "Accepted By Empty Stack".
  – The set of strings that cause the PDA to empty its stack, starting from the initial ID.

• These two methods are equivalent:
  – A language L has a PDA A that accepts it by final state if and only if L has a PDA B that accepts it by empty stack.
Let $P = (Q, \Sigma, \Gamma, \delta, q_0, Z_0, F)$ be a PDA. Then $L(P)$, the language of $P$ which accepts by final state, is:

$$L(P) = \{ w : (q_0, w, Z_0) \vdash^* (q, \varepsilon, \alpha) \}$$

for some state $q$ in $F$ and any stack string $\alpha$.

- Starting in the initial ID with $w$ waiting on the input, $P$ consumes $w$ from the input and enters an accepting state.
  - The contents of the stack at that time is irrelevant.
The Languages of a PDA

Acceptance By Empty Stack

Let $P = (Q, \Sigma, \Gamma, \delta, q_0, Z_0)$ be a PDA. Then $L(P)$, the language of $P$ which accepts by empty stack, is:

$$L(P) = \{ w : (q_0, w, Z_0) \vdash^* (q, \varepsilon, \varepsilon) \}$$

for any state $q$.

- Since final states are irrelevant for PDAs that accept by empty stack, we do not define final states for those PDAs.
  - That is, a PDA that accepts by empty stack is 6 tuple (not 7 tuple).

- $L(P)$ is the set of inputs $w$ that $P$ can consume and at the same time empty its stack.
  - Final states are irrelevant.
A PDA Accepts By Empty Stack

- A PDA $P_N = (\{q\},\{0,1\},\{P,0,1\},\delta,q,P)$ which accepts by empty stack.
- The language of this PDA is $\{ w\epsilon : w\epsilon\{0,1\}^* \}$.

\[
\begin{align*}
\epsilon,&/P0P0 \\
\epsilon,&/P1P1 \\
\epsilon,&/\epsilon \\
0,0,&/\epsilon \\
1,1,&/\epsilon \\
q & \quad \text{Diagram}
\end{align*}
\]

- A computation sequence for 0110:

\[
(q,0110,P) \vdash (q,0110,0P0) \vdash (q,110,P0) \vdash (q,110,1P10) \vdash (q,10,P10) \vdash (q,10,10) \\
\vdash (q,0,0) \vdash (q,\epsilon,\epsilon)
\]

- Since there is a computation starts with initial ID and ends with empty stack and empty string for the string 0110, the string 0110 is recognized by this PDA.
A PDA Accepts By Empty Stack

- A PDA $P_N = (\{q\}, \{0,1\}, \{P, 0, 1\}, \delta, q, P)$ which accepts by empty stack.
- The language of this PDA is $\{ w w^r : w \in \{0,1\}^* \}$.
- Since all computations do NOT end with an ID containing empty stack and empty string, the string 01 is NOT accepted by this PDA.
Equivalence of Language Definitions

**Theorem:**

- If $L = L(\mathcal{P}_F)$ for some PDA $\mathcal{P}_F = (Q, \Sigma, \Gamma, \delta, q_0, Z_0, F)$ which accepts by final state, then there exists another PDA $\mathcal{P}_N$ which accepts by empty stack such that $L = L(\mathcal{P}_N)$.

- If $L = L(\mathcal{P}_N)$ for some PDA $\mathcal{P}_N = (Q, \Sigma, \Gamma, \delta, q_0, Z_0)$ which accepts by empty stack, then there exists another PDA $\mathcal{P}_F$ which accepts by final state such that $L = L(\mathcal{P}_F)$. 
Creating an Equivalent PDA Accepting by Empty Stack from a PDA Accepting by Final State

**Proof:** We will construct a PDA $P_N$ which accepts by empty stack from a given PDA $P_F = (Q, \Sigma, \Gamma, \delta, q_0, Z_0, F)$ which accepts by final state.

- Let $P_N = (Q \cup \{p_0, e\}, \Sigma, \Gamma \cup \{X_0\}, \delta_N, p_0, X_0)$
  - The states of $P_N$ will contain two new extra states $p_0$ and $e$.
    - The state $p_0$ is the start state of $P_N$.
    - The state $e$ is an **erase state** which will empty the stack.
  - $P_N$ will have a new stack symbol $X_0$, and $X_0$ will be the initial stack symbol of $P_N$.
    - The new stack symbol $X_0$ is to guard the stack bottom against accidental emptying.
  - The transition function $\delta_N$ will contain everything in the transition function $\delta$ of $P_F$ and the following new transitions:
    - $\delta_N(p_0, \varepsilon, X_0) = \{(q_0, Z_0X_0)\}$ i.e. The new start state $p_0$ pushes the initial stack symbol $Z_0$ of $P_F$ into the stack and moves to the state $q_0$ which is the start state of $P_F$.
    - For any final state $f$ of $P_F$, $\delta_N(f, \varepsilon, Y) = \{(e, \varepsilon)\}$ for any stack symbol $Y$. i.e. A final state of $P_F$ can move to the new erase $e$ state by erasing the top of stack symbol.
    - $\delta_N(e, \varepsilon, Y) = \{(e, \varepsilon)\}$ i.e. The new erase state $e$ erases all symbols from the stack.
Proof (continued):

- From $P_F = (Q, \Sigma, \Gamma, \delta, q_0, Z_0, F)$ construct $P_N = (Q \cup \{p_0, e\}, \Sigma, \Gamma \cup \{X_0\}, \delta_N, p_0, X_0)$ as follows:

- Now, we must prove that $L(P_N) = L(P_F)$.
  - If $w \in L(P_F)$ then $w \in L(P_N)$. i.e. if $(q_0, w, Z_0) \vdash^*_F (f, \varepsilon, \alpha)$ then $(p_0, w, X_0) \vdash^*_N (e, \varepsilon, \varepsilon)$
  - If $w \in L(P_N)$ then $w \in L(P_F)$. i.e. if $(p_0, w, X_0) \vdash^*_N (e, \varepsilon, \varepsilon)$ then $(q_0, w, Z_0) \vdash^*_F (f, \varepsilon, \alpha)$
From a PDA Accepting by Final State to a PDA Accepting by Empty Stack: Example
Creating an Equivalent PDA Accepting by Final State from a PDA Accepting by Empty Stack

**Proof:** We will construct a PDA $P_F$ which accepts by final state from a given PDA $P_N = (Q, \Sigma, \Gamma, \delta, q_0, Z_0)$ which accepts by empty stack.

- Let $P_F = (Q \cup \{p_0, p_f\}, \Sigma, \Gamma \cup \{X_0\}, \delta_F, p_0, X_0, \{p_f\})$
  - The states of $P_F$ will contain two new extra states $p_0$ and $p_f$.
    - The state $p_0$ is the start state of $P_F$.
    - The state $p_f$ is only final state of $P_F$.
  - $P_F$ will have a new stack symbol $X_0$, and $X_0$ will be the initial stack symbol of $P_F$.
    - The new stack symbol $X_0$ is to guard the stack bottom against accidental emptying.
  - The transition function $\delta_F$ will contain everything in the transition function $\delta$ of $P_N$ and the following new transitions:
    - $\delta_F(p_0, \epsilon, X_0) = \{(q_0, Z_0, X_0)\}$ i.e. The new start state $p_0$ pushes the initial stack symbol $Z_0$ of $P_N$ into the stack and moves to the state $q_0$ which is the start state of $P_N$.
    - For any state $q$ of $P_N$, $\delta_F(q, \epsilon, X_0) = \{(p_f, \epsilon)\}$ i.e. Every state $q$ of $P_N$ can move to the new final state $p_f$ when the stack symbol is $X_0$ and erases the top of stack symbol.
Proof (continued):
From $P_N = (Q, \Sigma, \Gamma, \delta, q_0, Z_0)$ construct $P_F = (Q \cup \{p_0, p_f\}, \Sigma, \Gamma \cup \{X_0\}, \delta_F, p_0, X_0, \{p_f\})$ as follows:

- Now, we must prove that $L(P_F) = L(P_N)$.
  - If $w \in L(P_F)$ then $w \in L(P_N)$. i.e. if $(p_0, w, X_0) \vdash^*_F (p_f, \varepsilon, \varepsilon)$ then $(q_0, w, Z_0) \vdash^*_N (q, \varepsilon, \varepsilon)$ for any $q$
  - If $w \in L(P_N)$ then $w \in L(P_F)$. i.e. if $(q_0, w, Z_0) \vdash^*_N (q, \varepsilon, \varepsilon)$ for any $q$ then $(p_0, w, X_0) \vdash^*_F (p_f, \varepsilon, \varepsilon)$
From a PDA Accepting by Empty Stack to a PDA Accepting by Final State: Example
Equivalence of PDA's and CFG's
Equivalence of PDA's and CFG's

- The following three classes of languages are all the same class.
  1. The context-free languages, i.e., the languages defined by CFG's.
  2. The languages that are accepted by final state by some PDA.
  3. The languages that are accepted by empty stack by some PDA.

- We have already shown that (2) and (3) are the same.
- It turns out to be easiest next to show that (1) and (3) are the same, thus implying the equivalence of all three.
From Grammars to Pushdown Automata

• Given a CFG $G$, we construct a PDA that simulates the leftmost derivations of $G$.

• Any left-sentential form that is not a terminal string can be written as $xA\alpha$, where
  – $A$ is the leftmost variable,
  – $x$ is whatever terminals appear to the left of $A$, and
  – $\alpha$ is the string of terminals and variables that appear to the right of $A$.
  – If a left-sentential form consists of terminals only, then $A\alpha$ is $\varepsilon$.

• Let $xA\alpha \Rightarrow_{lm} x\beta\alpha$ be a derivation step from the left-sentential form $xA\alpha$.
  – This derivation step corresponds to the PDA having consumed $x$ and having $A$ on the top of the stack, and then the PDA on $\varepsilon$ it pops $A$ and pushes $\beta$ into the stack.
From Grammars to Pushdown Automata

PDA Construction from CFG

PDA Construction from CFG:

- Let $G = (V, T, R, S)$ be a CFG.
- Construct the PDA $P$ that accepts $L(G)$ by empty stack as follows:

  $$P = (\{q\}, T, V \cup T, \delta, q, S)$$

  where transition function $\delta$ is defined by:

1. For each variable $A$,

   $$\delta(q, \varepsilon, A) = \{(q, \beta) \mid A \rightarrow \beta \text{ is a production of } G\}$$

2. For each terminal $a$, $\delta(q, a, a) = \{(q, \varepsilon)\}$
From CFG to PDA - Example

- Let CFG $G = (\{P\}, \{0,1\}, \{P \rightarrow 0P0, P \rightarrow 1P1, P \rightarrow \varepsilon\}, P)$
- $L(G)$ is $\{ww^r : w \in \{0,1\}^*\}$

- We can construct PDA $A = (\{q\}, \{0,1\}, \{0,1,P\}, \delta, q, P)$ with following transitions.

$$
\begin{align*}
\delta(q, \varepsilon, P) &= \{(q, 0P0), (q, 1P1), (q, \varepsilon)\} \\
\delta(q, 0, 0) &= \{(q, \varepsilon)\} \\
\delta(q, 1, 1) &= \{(q, \varepsilon)\}
\end{align*}
$$

⊢ (q,10,10) ⊢ (q,0,0) ⊢ (q,ε,ε)

• A leftmost derivation sequence of 0111:

P ⇒ 0P0 ⇒ 01P10 ⇒ 0110
Theorem: If PDA $P$ is constructed from CFG $G$ by the construction algorithm then $L(P) = L(G)$.

Proof:

- We have to show that $(q,w,S) \overset{*}{\Rightarrow} (q,\varepsilon,\varepsilon)$ if and only if $S \Rightarrow^* w$

- We need to prove something more general:
  - We need to show that $(q,wx,S) \overset{*}{\Rightarrow} (q,x,\alpha)$ for any $x$ if and only if $S \Rightarrow^*_{lm} w\alpha$
  - After this proof, we can let $x=\alpha=\varepsilon$
    - Then $(q,w,S) \overset{*}{\Rightarrow} (q,\varepsilon,\varepsilon)$ if and only if $S \Rightarrow^* w$
    - That is, $w$ is in $L(P)$ if and only if $w$ is in $L(G)$.
Proof (Only-If Part):

- Suppose \((q,wx,S) \vdash^* (q,x,\alpha)\) for any \(x\).
- We have to show that \(S \Rightarrow^*_m w\alpha\)
- Proof is an induction on the number steps made by \(P\)

**Basis:** 0 steps

- Then \(\alpha=S\), \(w=\varepsilon\), and \(S \Rightarrow^*_m S\) is surely true.

**Induction:**

- Consider \(n\) moves of \(P\): \((q,wx,S) \vdash^* (q,x,\alpha)\) and assume the IH for sequences of \(n-1\) moves.
- There are two cases, depending on whether the last move uses a terminal or a variable on the top of stack.
Induction (cont.):

Case 1: The move sequence must be of the form \((q,yax,S) \vdash^* (q,ax,a\alpha) \vdash (q,x,\alpha)\), where \(ya = w\).
   
   - By the IH applied to the first \(n-1\) steps, \(S \Rightarrow_{lm}^* ya\alpha\).
   - But \(ya = w\), so \(S \Rightarrow_{lm}^* w\alpha\).

Case 2: The move sequence must be of the form \((q,wx,S) \vdash^* (q,x,A\beta) \vdash (q,x,\gamma\beta)\), where \(A \rightarrow \gamma\) is a production and \(\alpha = \gamma\beta\).
   
   - By the IH applied to the first \(n-1\) steps, \(S \Rightarrow_{lm}^* wA\beta\).
   - Thus, \(S \Rightarrow_{lm}^* w\gamma\beta = w\alpha\).
Proof (If Part):

- Suppose $S \Rightarrow_{lm}^* w\alpha$
- We have to show that $(q,wx,S) \vdash^* (q,x,\alpha)$ for any $x$.
- Proof is an induction on the length of the leftmost derivation.

- The proof is similar to Only-If part proof and it is in the book.
From a PDA Accepting with Empty Stack to a CFG

• Assume we have a PDA \( P = (Q, \Sigma, \Gamma, \delta, q_0, Z_0) \) which accepts with empty stack.
• We’ll construct a CFG \( G \) such that \( L(P) = L(G) \).

• Intuition:
  – \( G \) will have variables generating exactly the inputs that cause \( P \) to have the net effect of popping a stack symbol \( X \) while going from state \( p \) to state \( q \).
  – \( P \) never gets below this \( X \) while doing so.
Construct a CFG $G=(V,T,R,S)$ from PDA $P=(Q,\Sigma,\Gamma,\delta,q_0,Z_0)$ such that $L(P) = L(G)$.

Variables of $G$:

- G’s variables are of the form $[pXq]$ where $p \in Q$, $q \in Q$, $X \in \Gamma$,
  - The variable $[pXq]$ generates all and only the strings $w$ such that $(p,w,X) \vdash^* (q,\varepsilon,\varepsilon)$.
- In addition, $G$ will also have a start symbol $S$.
- Thus, $V = \{ [pXq] : p \in Q, q \in Q, X \in \Gamma \} \cup \{S\}$
Construct a CFG $G=(V,T,R,S)$ from PDA $P=(Q,\Sigma,\Gamma,\delta,q_0,Z_0)$ such that $L(P) = L(G)$.

Productions of $G$:

- Each production for $[pXq]$ comes from a move of $P$ in state $p$ with stack symbol $X$.

**CASE 1:** $\delta(p,a,X)$ contains $(q,\varepsilon)$.

- $G$ has the production $[pXq] \rightarrow a$ where $a \in \Sigma \cup \{\varepsilon\}$.
  - $[pXq]$ generates $a$, because reading $a$ is one way to pop $X$ and go from $p$ to $q$.

**CASE 2:** $\delta(p,a,X)$ contains $(r,Y)$ for some state $r$ and a stack symbol $Y$.

- For each state $q \in Q$, $G$ has the production $[pXq] \rightarrow a[rYq]$ where $a \in \Sigma \cup \{\varepsilon\}$.
  - We can erase $X$ and go from $p$ to $q$ by reading $a$ (entering state $r$ and replacing $X$ by $Y$) and then reading some $w$ that gets $P$ from $r$ to $q$ while erasing $Y$.
  - **Note:** $[pXq] \Rightarrow^* aw$ whenever $[rYq] \Rightarrow^* w$. 

From a PDA to a CFG

Productions of $G$:

**GENERAL CASE:** $\delta(p,a,X)$ contains $(r,Y_1\ldots Y_k)$ for some state $r$ and $k \geq 2$.

- Generate a family of productions (For all states $q, s_1, \ldots, s_{k-1}$)

$$[pXq] \rightarrow a [rY_1s_1] [s_1Y_2s_2] \ldots [s_{k-2}Y_{k-1}s_{k-2}] [s_{k-1}Y_kq]$$

**When k=2:** $\delta(p,a,X)$ contains $(r,YZ)$ for some state $r$

- Now, $P$ has replaced $X$ by $YZ$.
- To have the net effect of erasing $X$, $P$ must erase $Y$, going from state $r$ to some state $s$, and then erase $Z$, going from $s$ to $q$.
- Since we do not know state $s$, we must generate a family of productions:

$$[pXq] \rightarrow a[rYs][sZq] \quad \text{for all states } s.$$  

- Note: $[pXq] \Rightarrow^* awx$ whenever $[rYs] \Rightarrow^* w$ and $[sZq] \Rightarrow^* x$. 
From a PDA to a CFG

Completion of the Construction:

• We can prove that \((q_0, w, Z_0) \rightarrow^* (p, \varepsilon, \varepsilon)\) if and only if \([q_0Z_0p] \Rightarrow^* w\).
• But state \(p\) can be anything.
• Thus, add productions \(S \rightarrow [q_0Z_0p]\) for each state \(p\).
From a PDA to a CFG: Example

- Convert the PDA $P=\langle\{p,q\},\{0,1\},\{X,Z_0\},\delta,q,Z_0\rangle$ where $\delta$ is given by:

  1. $\delta(q, 1, Z_0) = \{(q, XZ_0)\}$
  2. $\delta(q, 1, X) = \{(q, XX)\}$
  3. $\delta(q, 0, X) = \{(p, X)\}$
  4. $\delta(q, \epsilon, X) = \{(q, \epsilon)\}$
  5. $\delta(p, 1, X) = \{(p, \epsilon)\}$
  6. $\delta(p, 0, Z_0) = \{(q, Z_0)\}$

- We get $G=\langle\{[pXp],[pXq],[pZ_0p],[pZ_0q],S\}, \{0,1\}, R, S\rangle$
From a PDA to a CFG: Example

\[ G = (\{ [pXp], [pXq], [pZ_0p], [pZ_0q], S \}, \{0, 1\}, R, S) \]

and productions in \( R \) are:

\[ S \rightarrow [qZ_0q][qZ_0p] \]

From 1. \( \delta(q, 1, Z_0) = \{(q, XZ_0)\} \)

\[ [qZ_0q] \rightarrow 1[qXq][qZ_0q] \]
\[ [qZ_0q] \rightarrow 1[qXp][pZ_0q] \]
\[ [qZ_0p] \rightarrow 1[qXq][qZ_0p] \]
\[ [qZ_0p] \rightarrow 1[qXp][pZ_0p] \]

From 2. \( \delta(q, 1, X) = \{(q, XX)\} \)

\[ [qXq] \rightarrow 1[qXq][qXq] \]
\[ [qXq] \rightarrow 1[qXp][pXq] \]
\[ [qXp] \rightarrow 1[qXq][qXp] \]
\[ [qXp] \rightarrow 1[qXp][pXp] \]

From 3. \( \delta(q, 0, X) = \{(p, X)\} \)

\[ [qXq] \rightarrow 0[pXq] \]
\[ [qXp] \rightarrow 0[pXp] \]

From 4. \( \delta(q, \epsilon, X) = \{(q, \epsilon)\} \)

\[ [qXq] \rightarrow \epsilon \]

From 5. \( \delta(p, 1, X) = \{(p, \epsilon)\} \)

\[ [pXp] \rightarrow 1 \]

From 6. \( \delta(p, 0, Z_0) = \{(q, Z_0)\} \)

\[ [pZ_0q] \rightarrow 0[qZ_0q] \]
\[ [pZ_0p] \rightarrow 0[qZ_0p] \]
Deterministic Pushdown Automata (DPDA)
While PDA's are by definition allowed to be nondeterministic, the deterministic subcase is quite important.

In particular, parsers generally behave like deterministic PDA's, so the class of languages that can be accepted by these automata is interesting for the insights it gives us into what constructs are suitable for use in programming languages.

A PDA $P = (Q, \Sigma, \Gamma, \delta, q_0, Z_0, F)$ is deterministic iff

1. $(q, a, X)$ is always empty or a singleton where $a \in \Sigma$, or $a$ is $\varepsilon$.
2. If $(q, a, X)$ is nonempty where $a \in \Sigma$, then $(q, \varepsilon, X)$ must be empty.
DPDA - Example

\[ L = \{ \text{wc} w^R : w \in \{0,1\}^* \} \]

- \( L \) is recognized by the following DPDA:

\[
\begin{align*}
0, Z_0 &/ 0 Z_0 \\
1, Z_0 &/ 1 Z_0 \\
0, 0 &/ 0 0 \\
0, 1 &/ 0 1 \\
1, 0 &/ 1 0 \\
1, 1 &/ 1 1 \\
0, 0 &/ \varepsilon \\
1, 1 &/ \varepsilon \\
\end{align*}
\]
If \( L \) is a regular language, then \( L = L(P) \) for some DPDA \( P \).

- regular languages \( \subset \) languages of DPDAs

There are languages that are not regular, but there are DPDAs for them.

- \( \{ wcw^R : w \in \{0,1\}^* \} \) is a member of languages of DPDAs but it is not regular.

There are context free languages which are NOT members of languages of DPDAs.

- \( \{ ww^R : w \in \{0,1\}^* \} \) is NOT a member of languages of DPDAs. i.e. there is NO DPDA for the language \( \{ ww^R : w \in \{0,1\}^* \} \).

- languages of DPDAs \( \subset \) context free languages
DPDA Properties

There are NO DPDAs for inherently ambiguous CFLs.

For a given unambiguous grammar we may NOT find a DPDA.

- \( \{ \text{ww}^R : w \in \{0,1\}^* \} \) has unambiguous grammar \( S \rightarrow 0S0 \mid 1S1 \mid \varepsilon \)
- But \( \{ \text{ww}^R : w \in \{0,1\}^* \} \) is NOT a member of languages of DPDAs.

We can always find an unambiguous grammar for the language of a given DPDA.

- The languages of DPDAs are equal to languages of deterministic context free grammars.
- Each LR(k) grammar is an unambiguous grammar, but not all unambiguous grammars are LR(k) grammars.
- The languages of LR(k) grammars are very close to languages of deterministic context free grammars (languages of DPDAs).
- LR(k) grammars are widely used in the parsing of programming languages (LR parsers).
Formal Languages -- So far
